Package 'bnlearn'

January 27, 2015

Type Package

Title Bayesian Network Structure Learning, Parameter Learning and Inference

Version 3.7.1

Date 2015-01-23

Depends R (>= 2.14.0)

Imports methods

Suggests parallel, graph, Rgraphviz, lattice, gRain

Author Marco Scutari

Maintainer Marco Scutari <marco.scutari@gmail.com>

Description Bayesian network structure learning, parameter learning and inference.
This package implements constraint-based (GS, IAMB, Inter-IAMB, Fast-IAMB, MMPC, Hiton-PC), pairwise (ARACNE and Chow-Liu), score-based (Hill-Climbing and Tabu Search) and hybrid (MMHC and RSMAX2) structure learning algorithms for discrete, Gaussian and conditional Gaussian networks, along with many score functions and conditional independence tests.
The Naive Bayes and the Tree-Augmented Naive Bayes (TAN) classifiers are also implemented.
Some utility functions (model comparison and manipulation, random data generation, arc orientation testing, simple and advanced plots) are included, as well as support for parameter estimation (maximum likelihood and Bayesian) and inference, conditional probability queries and cross-validation. Development snapshots with the latest bugfixes are available from www.bnlearn.com.

R topics documented:

`bnlearn-package` *Bayesian network structure learning, parameter learning and inference.*

Description

Bayesian network structure learning (via constraint-based, score-based and hybrid algorithms), parameter learning (via ML and Bayesian estimators) and inference.

Details

Package:	bnlearn
Type:	Package
Version:	3.7.1
Date:	2015-01-23
License:	GPLv2 or later

This package implements some algorithms for learning the structure of Bayesian networks.

Constraint-based algorithms, also known as *conditional independence learners*, are all optimized derivatives of the *Inductive Causation* algorithm (Verma and Pearl, 1991). These algorithms use conditional independence tests to detect the Markov blankets of the variables, which in turn are used to compute the structure of the Bayesian network.

Score-based learning algorithms are general purpose heuristic optimization algorithms which rank network structures with respect to a goodness-of-fit score.

Hybrid algorithms combine aspects of both constraint-based and score-based algorithms, as they use conditional independence tests (usually to reduce the search space) and network scores (to find the optimal network in the reduced space) at the same time.

Several functions for parameter estimation, parametric inference, bootstrap, cross-validation and stochastic simulation are available. Furthermore, advanced plotting capabilities are implemented on top of the **Rgraphviz** and **lattice** packages.

Available constraint-based learning algorithms

- *Grow-Shrink* (`gs`): based on the *Grow-Shrink Markov Blanket*, the first (and simplest) Markov blanket detection algorithm used in a structure learning algorithm.

- *Incremental Association* (`iamb`): based on the Markov blanket detection algorithm of the same name, which is based on a two-phase selection scheme (a forward selection followed by an attempt to remove false positives).
- *Fast Incremental Association* (`fast.iamb`): a variant of IAMB which uses speculative stepwise forward selection to reduce the number of conditional independence tests.
- *Interleaved Incremental Association* (`inter.iamb`): another variant of IAMB which uses forward stepwise selection to avoid false positives in the Markov blanket detection phase.

This package includes three implementations of each algorithm:

- an optimized implementation (used when the `optimized` parameter is set to `TRUE`), which uses backtracking to initialize the learning process of each node.
- an unoptimized implementation (used when the `optimized` parameter is set to `FALSE`) which is better at uncovering possible erratic behaviour of the statistical tests.
- a cluster-aware implementation, which requires a running cluster set up with the `makeCluster` function from the **parallel** package. See parallel integration for a sample usage.

The computational complexity of these algorithms is polynomial in the number of tests, usually $O(N^2)$ ($O(N^4)$ in the worst case scenario), where N is the number of variables. Execution time scales linearly with the size of the data set.

Available score-based learning algorithms

- *Hill-Climbing* (`hc`): a *hill climbing* greedy search on the space of the directed graphs. The optimized implementation uses score caching, score decomposability and score equivalence to reduce the number of duplicated tests.
- *Tabu Search* (`tabu`): a modified hill climbing able to escape local optima by selecting a network that minimally decreases the score function.

Random restart with a configurable number of perturbing operations is implemented for both algorithms.

Available hybrid learning algorithms

- *Max-Min Hill-Climbing* (`mmhc`): a hybrid algorithm which combines the Max-Min Parents and Children algorithm (to restrict the search space) and the Hill-Climbing algorithm (to find the optimal network structure in the restricted space).
- *Restricted Maximization* (`rsmax2`): a more general implementation of the Max-Min Hill-Climbing, which can use any combination of constraint-based and score-based algorithms.

Other (constraint-based) local discovery algorithms

These algorithms learn the structure of the undirected graph underlying the Bayesian network, which is known as the *skeleton* of the network or the *(partial) correlation graph*. Therefore all the arcs are undirected, and no attempt is made to detect their orientation. They are often used in hybrid learning algorithms.

- *Max-Min Parents and Children* (`mmpc`): a forward selection technique for neighbourhood detection based on the maximization of the minimum association measure observed with any subset of the nodes selected in the previous iterations.

- *Hiton Parents and Children* (`si.hiton.pc`): a fast forward selection technique for neighbourhood detection designed to exclude nodes early based on the marginal association. The implementation follows the Semi-Interleaved variant of the algorithm.
- *Chow-Liu* (`chow.liu`): an application of the minimum-weight spanning tree and the information inequality. It learn the tree structure closest to the true one in the probability space.
- *ARACNE* (`aracne`): an improved version of the Chow-Liu algorithm that is able to learn polytrees.

All these algorithms have three implementations (unoptimized, optimized and cluster-aware) like other constraint-based algorithms.

Bayesian Network classifiers

The algorithms are aimed at classification, and favour predictive power over the ability to recover the correct network structure. The implementation in **bnlearn** assumes that all variables, including the classifiers, are discrete.

- *Naive Bayes* (`naive.bayes`): a very simple algorithm assuming that all classifiers are independent and using the posterior probability of the target variable for classification.
- *Tree-Augmented Naive Bayes* (`tree.bayes`): a improvement over naive Bayes, this algorithms uses Chow-Liu to approximate the dependence structure of the classifiers.

Available (conditional) independence tests

The conditional independence tests used in *constraint-based* algorithms in practice are statistical tests on the data set. Available tests (and the respective labels) are:

- *discrete case* (categorical variables)
  - *mutual information*: an information-theoretic distance measure. It's proportional to the log-likelihood ratio (they differ by a $2n$ factor) and is related to the deviance of the tested models. The asymptotic χ^2 test (`mi` and `mi-adf`, with adjusted degrees of freedom), the Monte Carlo permutation test (`mc-mi`), the sequential Monte Carlo permutation test (`smc-mi`), and the semiparametric test (`sp-mi`) are implemented.
  - *shrinkage estimator* for the *mutual information* (`mi-sh`): an improved asymptotic χ^2 test based on the James-Stein estimator for the mutual information.
  - *Pearson's* X^2: the classical Pearson's X^2 test for contingency tables. The asymptotic χ^2 test (`x2` and `x2-adf`, with adjusted degrees of freedom), the Monte Carlo permutation test (`mc-x2`), the sequential Monte Carlo permutation test (`smc-x2`) and semiparametric test (`sp-x2`) are implemented.
- *discrete case* (ordered factors)
  - *Jonckheere-Terpstra*: a trend test for ordinal variables. The asymptotic normal test (`jt`), the Monte Carlo permutation test (`mc-jt`) and the sequential Monte Carlo permutation test (`smc-jt`) are implemented.
- *continuous case* (normal variables)
  - *linear correlation*: Pearson's linear correlation. The exact Student's t test (`cor`), the Monte Carlo permutation test (`mc-cor`) and the sequential Monte Carlo permutation test (`smc-cor`) are implemented.

  - *Fisher's Z*: a transformation of the linear correlation with asymptotic normal distribution. Used by commercial software (such as TETRAD II) for the PC algorithm (an R implementation is present in the `pcalg` package on CRAN). The asymptotic normal test (`zf`), the Monte Carlo permutation test (`mc-zf`) and the sequential Monte Carlo permutation test (`smc-zf`) are implemented.
  - *mutual information*: an information-theoretic distance measure. Again it is proportional to the log-likelihood ratio (they differ by a $2n$ factor). The asymptotic χ^2 test (`mi-g`), the Monte Carlo permutation test (`mc-mi-g`) and the sequential Monte Carlo permutation test (`smc-mi-g`) are implemented.
  - *shrinkage estimator* for the *mutual information* (`mi-g-sh`): an improved asymptotic χ^2 test based on the James-Stein estimator for the mutual information.
- *hybrid case* (mixed discrete and normal variables)
  - *mutual information*: an information-theoretic distance measure. Again it is proportional to the log-likelihood ratio (they differ by a $2n$ factor). Only the asymptotic χ^2 test (`mi-cg`) is implemented.

Available network scores

Available scores (and the respective labels) are:

- *discrete case* (categorical variables)
  - the multinomial *log-likelihood* (`loglik`) score, which is equivalent to the *entropy measure* used in Weka.
  - the *Akaike Information Criterion* score (`aic`).
  - the *Bayesian Information Criterion* score (`bic`), which is equivalent to the *Minimum Description Length* (MDL) and is also known as *Schwarz Information Criterion*.
  - the logarithm of the *Bayesian Dirichlet equivalent* score (`bde`), a score equivalent Dirichlet posterior density.
  - the logarithm of the modified *Bayesian Dirichlet equivalent* score (`mbde`) for mixtures of experimental and observational data (not score equivalent).
  - the logarithm of the *K2* score (`k2`), a Dirichlet posterior density (not score equivalent).
- *continuous case* (normal variables)
  - the multivariate Gaussian *log-likelihood* (`loglik-g`) score.
  - the corresponding *Akaike Information Criterion* score (`aic-g`).
  - the corresponding *Bayesian Information Criterion* score (`bic-g`).
  - a score equivalent *Gaussian posterior density* (`bge`).
- *hybrid case* (mixed discrete and normal variables)
  - the conditional linear Gaussian *log-likelihood* (`loglik-cg`) score.
  - the corresponding *Akaike Information Criterion* score (`aic-cg`).
  - the corresponding *Bayesian Information Criterion* score (`bic-cg`).

Whitelist and blacklist support

All learning algorithms support arc whitelisting and blacklisting:

- blacklisted arcs are never present in the graph.

- arcs whitelisted in one direction only (i.e. $A \rightarrow B$ is whitelisted but $B \rightarrow A$ is not) have the respective reverse arcs blacklisted, and are always present in the graph.
- arcs whitelisted in both directions (i.e. both $A \rightarrow B$ and $B \rightarrow A$ are whitelisted) are present in the graph, but their direction is set by the learning algorithm.

Any arc whitelisted and blacklisted at the same time is assumed to be whitelisted, and is thus removed from the blacklist.

In algorithms that learn undirected graphs, such as ARACNE and Chow-Liu, an arc must be blacklisted in both directions to blacklist the underlying undirected arc.

Error detection and correction: the strict mode

Optimized implementations of constraint-based algorithms rely heavily on backtracking to reduce the number of tests needed by the learning algorithm. This approach may sometimes hide errors either in the Markov blanket or the neighbourhood detection steps, such as when hidden variables are present or there are external (logical) constraints on the interactions between the variables.

On the other hand, in the unoptimized implementations of constraint-based algorithms the learning of the Markov blanket and neighbourhood of each node is completely independent from the rest of the learning process. Thus it may happen that the Markov blanket or the neighbourhoods are not symmetric (i.e. A is in the Markov blanket of B but not vice versa), or that some arc directions conflict with each other.

The `strict` parameter enables some measure of error correction for such inconsistencies, which may help to retrieve a good model when the learning process would otherwise fail:

- if `strict` is set to `TRUE`, every error stops the learning process and results in an error message.
- if `strict` is set to `FALSE`:
  1. v-structures are applied to the network structure in lowest-p.value order; if any arc is already oriented in the opposite direction, the v-structure is discarded.
  2. nodes which cause asymmetries in any Markov blanket are removed from that Markov blanket; they are treated as false positives.
  3. nodes which cause asymmetries in any neighbourhood are removed from that neighbourhood; again they are treated as false positives (see Tsamardinos, Brown and Aliferis, 2006).

  Each correction results in a warning.

Examples

```
library(bnlearn)
data(learning.test)

## Simple learning
# first try the Grow-Shrink algorithm
res = gs(learning.test)
# plot the network structure.
plot(res)
# now try the Incremental Association algorithm.
res2 = iamb(learning.test)
# plot the new network structure.
plot(res2)
# the network structures seem to be identical, don't they?
all.equal(res, res2)
# how many tests each of the two algorithms used?
ntests(res)
ntests(res2)
# and the unoptimized implementation of these algorithms?
## Not run: ntests(gs(learning.test, optimized = FALSE))
## Not run: ntests(iamb(learning.test, optimized = FALSE))

## Greedy search
res = hc(learning.test)
plot(res)

## Another simple example (Gaussian data)
data(gaussian.test)
# first try the Grow-Shrink algorithm
res = gs(gaussian.test)
plot(res)

## Blacklist and whitelist use
# the arc B - F should not be there?
blacklist = data.frame(from = c("B", "F"), to = c("F", "B"))
blacklist
res3 = gs(learning.test, blacklist = blacklist)
plot(res3)
# force E - F direction (E -> F).
whitelist = data.frame(from = c("E"), to = c("F"))
```

```
whitelist
res4 = gs(learning.test, whitelist = whitelist)
plot(res4)
# use both blacklist and whitelist.
res5 = gs(learning.test, whitelist = whitelist, blacklist = blacklist)
plot(res5)

## Debugging
# use the debugging mode to see the learning algorithms
# in action.
res = gs(learning.test, debug = TRUE)
res = hc(learning.test, debug = TRUE)
# log the learning process for future reference.
## Not run:
sink(file = "learning-log.txt")
res = gs(learning.test, debug = TRUE)
sink()
# if something seems wrong, try the unoptimized version
# in strict mode (inconsistencies trigger errors):
res = gs(learning.test, optimized = FALSE, strict = TRUE, debug = TRUE)
# or disable strict mode to let the algorithm fix errors on the fly:
res = gs(learning.test, optimized = FALSE, strict = FALSE, debug = TRUE)

## End(Not run)
```

`alarm` *ALARM Monitoring System (synthetic) data set*

Description

The ALARM ("A Logical Alarm Reduction Mechanism") is a Bayesian network designed to provide an alarm message system for patient monitoring.

Usage

```
data(alarm)
```

Format

The `alarm` data set contains the following 37 variables:

- `CVP` (*central venous pressure*): a three-level factor with levels `LOW`, `NORMAL` and `HIGH`.
- `PCWP` (*pulmonary capillary wedge pressure*): a three-level factor with levels `LOW`, `NORMAL` and `HIGH`.
- `HIST` (*history*): a two-level factor with levels `TRUE` and `FALSE`.
- `TPR` (*total peripheral resistance*): a three-level factor with levels `LOW`, `NORMAL` and `HIGH`.
- `BP` (*blood pressure*): a three-level factor with levels `LOW`, `NORMAL` and `HIGH`.
- `CO` (*cardiac output*): a three-level factor with levels `LOW`, `NORMAL` and `HIGH`.

- HRBP (*heart rate / blood pressure*): a three-level factor with levels LOW, NORMAL and HIGH.
- HREK (*heart rate measured by an EKG monitor*): a three-level factor with levels LOW, NORMAL and HIGH.
- HRSA (*heart rate / oxygen saturation*): a three-level factor with levels LOW, NORMAL and HIGH.
- PAP (*pulmonary artery pressure*): a three-level factor with levels LOW, NORMAL and HIGH.
- SAO2 (*arterial oxygen saturation*): a three-level factor with levels LOW, NORMAL and HIGH.
- FIO2 (*fraction of inspired oxygen*): a two-level factor with levels LOW and NORMAL.
- PRSS (*breathing pressure*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- ECO2 (*expelled CO2*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- MINV (*minimum volume*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- MVS (*minimum volume set*): a three-level factor with levels LOW, NORMAL and HIGH.
- HYP (*hypovolemia*): a two-level factor with levels TRUE and FALSE.
- LVF (*left ventricular failure*): a two-level factor with levels TRUE and FALSE.
- APL (*anaphylaxis*): a two-level factor with levels TRUE and FALSE.
- ANES (*insufficient anesthesia/analgesia*): a two-level factor with levels TRUE and FALSE.
- PMB (*pulmonary embolus*): a two-level factor with levels TRUE and FALSE.
- INT (*intubation*): a three-level factor with levels NORMAL, ESOPHAGEAL and ONESIDED.
- KINK (*kinked tube*): a two-level factor with levels TRUE and FALSE.
- DISC (*disconnection*): a two-level factor with levels TRUE and FALSE.
- LVV (*left ventricular end-diastolic volume*): a three-level factor with levels LOW, NORMAL and HIGH.
- STKV (*stroke volume*): a three-level factor with levels LOW, NORMAL and HIGH.
- CCHL (*catecholamine*): a two-level factor with levels NORMAL and HIGH.
- ERLO (*error low output*): a two-level factor with levels TRUE and FALSE.
- HR (*heart rate*): a three-level factor with levels LOW, NORMAL and HIGH.
- ERCA (*electrocauter*): a two-level factor with levels TRUE and FALSE.
- SHNT (*shunt*): a two-level factor with levels NORMAL and HIGH.
- PVS (*pulmonary venous oxygen saturation*): a three-level factor with levels LOW, NORMAL and HIGH.
- ACO2 (*arterial CO2*): a three-level factor with levels LOW, NORMAL and HIGH.
- VALV (*pulmonary alveoli ventilation*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- VLNG (*lung ventilation*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- VTUB (*ventilation tube*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.
- VMCH (*ventilation machine*): a four-level factor with levels ZERO, LOW, NORMAL and HIGH.

graphviz.plot(res)
## End(Not run)
```

`arc operations` *Drop, add or set the direction of an arc or an edge*

Description

Drop, add or set the direction of an arc or an edge.

Usage

```
# arc operations.
set.arc(x, from, to, check.cycles = TRUE, debug = FALSE)
drop.arc(x, from, to, debug = FALSE)
reverse.arc(x, from, to, check.cycles = TRUE, debug = FALSE)

# edge (i.e. undirected arc) operations
set.edge(x, from, to, check.cycles = TRUE, debug = FALSE)
drop.edge(x, from, to, debug = FALSE)
```

Arguments

`x`	an object of class bn.
`from`	a character string, the label of a node.

to	a character string, the label of another node.
check.cycles	a boolean value. If TRUE the graph is tested for acyclicity; otherwise the graph is returned anyway.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The set.arc function operates in the following way:

- if there is no arc between from and to, the arc from → to is added.
- if there is an undirected arc between from and to, its direction is set to from → to.
- if the arc to → from is present, it is reversed.
- if the arc from → to is present, no action is taken.

The drop.arc function operates in the following way:

- if there is no arc between from and to, no action is taken.
- if there is a directed or an undirected arc between from and to, it is dropped regardless of its direction.

The reverse.arc function operates in the following way:

- if there is no arc between from and to, it returns an error.
- if there is an undirected arc between from and to, it returns an error.
- if the arc to → from is present, it is reversed.
- if the arc from → to is present, it is reversed.

The set.edge function operates in the following way:

- if there is no arc between from and to, the undirected arc from - to is added.
- if there is an undirected arc between from and to, no action is taken.
- if either the arc from → to or the arc to → from are present, they are replaced with the undirected arc from - to.

The drop.edge function operates in the following way:

- if there is no undirected arc between from and to, no action is taken.
- if there is an undirected arc between from and to, it is removed.
- if there is a directed arc between from and to, no action is taken.

Value

All functions return invisibly an updated copy of x.

Author(s)

Marco Scutari

Examples

```
data(learning.test)
res = gs(learning.test)

## use debug = TRUE to get more information.
set.arc(res, "A", "B")
drop.arc(res, "A", "B")
drop.edge(res, "A", "B")
reverse.arc(res, "A", "D")
```

---

arc.strength *Measure arc strength*

Description

Measure the strength of the probabilistic relationships expressed by the arcs of a Bayesian network, and use model averaging to build a network containing only the significant arcs.

Usage

```
# strength of the arcs present in x.
arc.strength(x, data, criterion = NULL, ..., debug = FALSE)
# strength of all possible arcs, as learned from bootstrapped data.
boot.strength(data, cluster = NULL, R = 200, m = nrow(data),
  algorithm, algorithm.args = list(), cpdag = TRUE, debug = FALSE)
# strength of all possible arcs, from a list of custom networks.
custom.strength(networks, nodes, weights = NULL, cpdag = TRUE, debug = FALSE)

# averaged network structure.
averaged.network(strength, nodes, threshold)
```

Arguments

x	an object of class bn.
networks	a list, containing either object of class bn or arc sets (matrices or data frames with two columns, optionally labeled "from" and "to").
data	a data frame containing the data the Bayesian network was learned from.
cluster	an optional cluster object from package **parallel**. See parallel integration for details and a simple example.
strength	an object of class bn.strength, see below.
threshold	a numeric value, the minimum strength required for an arc to be included in the averaged network. The default value is the threshold attribute of the strength argument.
nodes	a vector of character strings, the labels of the nodes in the network. In averaged.network, it defaults to the set of the unique node labels in the strength argument.

criterion	a character string, the label of a score function or an independence test. See bnlearn-package for details.
R	a positive integer, the number of bootstrap replicates.
m	a positive integer, the size of each bootstrap replicate.
weights	a vector of non-negative numbers, to be used as weights when averaging network structures to compute strength coefficients. If NULL, weights are assumed to be uniform.
cpdag	a boolean value. If TRUE the (PDAG of) the equivalence class is used instead of the network structure itself. It should make it easier to identify score-equivalent arcs.
algorithm	a character string, the learning algorithm to be applied to the bootstrap replicates. Possible values are gs, iamb, fast.iamb, inter.iamb, mmpc, hc, tabu, mmhc and rsmax2. See bnlearn-package and the documentation of each algorithm for details.
algorithm.args	a list of extra arguments to be passed to the learning algorithm.
...	additional tuning parameters for the network score (if criterion is the label of a score function, see score for details), the conditional independence test (currently the only one is B, the number of permutations).
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

If criterion is a conditional independence test, the strength is a p-value (so the lower the value, the stronger the relationship). The only possible additional parameter is B, the number of permutations to be generated for each permutation test.

If criterion is the label of a score function, the strength is measured by the score gain/loss which would be caused by the arc's removal. There may be additional parameters depending on the choice of the score, see score for details.

Model averaging is supported for objects of class bn.strength returned by boot.strength, by custom.strength, or by arc.strength with criterion set to bootstrap. The returned network contains the arcs whose strength is greater than the threshold attribute of the bn.strength object passed to averaged.network.

Value

arc.strength, boot.strength and custom.strength return an object of class bn.strength; boot.strength and custom.strength also include information about the relative probabilities of arc directions.

averaged.network returns an object of class bn.

See bn.strength class and bn-class for details.

Note

averaged.network typically returns a completely directed graph; an arc can be undirected if and only if the probabiliy of each of its directions is exactly 0.5. This may happen, for example, if the arc is undirected in all the networks being averaged.

```
data(learning.test)
res = gs(learning.test)
res = set.arc(res, "A", "B")
arc.strength(res, learning.test)

## Not run:
arcs = boot.strength(learning.test, algorithm = "hc")
arcs[(arcs$strength > 0.85) & (arcs$direction >= 0.5), ]
averaged.network(arcs)

start = random.graph(nodes = names(learning.test), num = 50)
netlist = lapply(start, function(net) {
  hc(learning.test, score = "bde", iss = 10, start = net) })
arcs = custom.strength(netlist, nodes = names(learning.test),
         cpdag = FALSE)
arcs[(arcs$strength > 0.85) & (arcs$direction >= 0.5), ]
modelstring(averaged.network(arcs))

## End(Not run)
```

---

asia *Asia (synthetic) data set by Lauritzen and Spiegelhalter*

Description

Small synthetic data set from Lauritzen and Spiegelhalter (1988) about lung diseases (tuberculosis, lung cancer or bronchitis) and visits to Asia.

Usage

```
data(asia)
```

Format

The `asia` data set contains the following variables:

- `D` (*dyspnoea*), a two-level factor with levels `yes` and `no`.
- `T` (*tuberculosis*), a two-level factor with levels `yes` and `no`.
- `L` (*lung cancer*), a two-level factor with levels `yes` and `no`.
- `B` (*bronchitis*), a two-level factor with levels `yes` and `no`.
- `A` (*visit to Asia*), a two-level factor with levels `yes` and `no`.
- `S` (*smoking*), a two-level factor with levels `yes` and `no`.
- `X` (*chest X-ray*), a two-level factor with levels `yes` and `no`.
- `E` (*tuberculosis versus lung cancer/bronchitis*), a two-level factor with levels `yes` and `no`.

Note

Lauritzen and Spiegelhalter (1988) motivate this example as follows:

"Shortness-of-breath (dyspnoea) may be due to tuberculosis, lung cancer or bronchitis, or none of them, or more than one of them. A recent visit to Asia increases the chances of tuberculosis, while smoking is known to be a risk factor for both lung cancer and bronchitis. The results of a single chest X-ray do not discriminate between lung cancer and tuberculosis, as neither does the presence or absence of dyspnoea."

Standard learning algorithms are not able to recover the true structure of the network because of the presence of a node (`E`) with conditional probabilities equal to both 0 and 1. Monte Carlo tests seems to behvae better than their parametric counterparts.

The complete BN can be downloaded from http://www.bnlearn.com/bnrepository.

Examples

```
# load the data and build the correct network from the model string.
data(asia)
res = empty.graph(names(asia))
modelstring(res) = "[A][S][T|A][L|S][B|S][D|B:E][E|T:L][X|E]"
plot(res)
```

bn class *The bn class structure*

Description

The structure of an object of S3 class bn.

Details

An object of class bn is a list containing at least the following components:

- learning: a list containing some information about the results of the learning algorithm. It's never changed afterward.
  - whitelist: a sanitized copy of the whitelist parameter (a two-column matrix, whose columns are labeled from and to).
  - blacklist: a sanitized copy of the blacklist parameter (a two-column matrix, whose columns are labeled from and to).
  - test: the label of the conditional independence test used by the learning algorithm (a character string). The label of the network score is used for score-based and hybrid algorithms, and "none" for randomly generated graphs.
  - ntests: the number of conditional independence tests or score comparisons used in the learning (an integer value).
  - algo: the label of the learning algorithm or the random generation algorithm used to generate the network (a character string).
  - args: a list. The values of the parameters of either the conditional tests or the scores used in the learning process. Only the relevant ones are stored, so this may be an empty list.
    * alpha: the target nominal type I error rate (a numeric value) of the conditional independence tests.
    * iss: a positive numeric value, the imaginary sample size used by the bge and bde scores.
    * phi: a character string, either heckerman or bottcher; used by the bge score.
    * k: a positive numeric value, the penalty per parameter used by the aic, aic-g, bic and bic-g scores.
    * prob: the probability of each arc to be present in a graph generated by the ordered graph generation algorithm.
    * burn.in: the number of iterations for the ic-dag graph generation algorithm to converge to a stationary (and uniform) probability distribution.
    * max.degree: the maximum degree for any node in a graph generated by the ic-dag graph generation algorithm.
    * max.in.degree: the maximum in-degree for any node in a graph generated by the ic-dag graph generation algorithm.
    * max.out.degree: the maximum out-degree for any node in a graph generated by the ic-dag graph generation algorithm.
    * training: a character string, the label of the training node in a Bayesian network classifier.

    * threshold: the threshold used to determine which arcs are significant when averaging network structures.

- nodes: a list. Each element is named after a node and contains the following elements:
  - mb: the Markov blanket of the node (a vector of character strings).
  - nbr: the neighbourhood of the node (a vector of character strings).
  - parents: the parents of the node (a vector of character strings).
  - children: the children of the node (a vector of character strings).
- arcs: the arcs of the Bayesian network (a two-column matrix, whose columns are labeled from and to). Undirected arcs are stored as two directed arcs with opposite directions between the corresponding incident nodes.

Additional (optional) components under learning:

- optimized: whether additional optimizations have been used in the learning algorithm (a boolean value).
- restrict: the label of the constraint-based algorithm used in the "Restrict" phase of a hybrid learning algorithm (a character string).
- rtest: the label of the conditional independence test used in the "Restrict" phase of a hybrid learning algorithm (a character string).
- maximize: the label of the score-based algorithm used in the "Maximize" phase of a hybrid learning algorithm (a character string).
- maxscore: the label of the network score used in the "Maximize" phase of a hybrid learning algorithm (a character string).

bn.boot *Parametric and nonparametric bootstrap of Bayesian networks*

Description

Apply a user-specified function to the Bayesian network structures learned from bootstrap samples of the original data.

Usage

```
bn.boot(data, statistic, R = 200, m = nrow(data), sim = "ordinary",
  algorithm, algorithm.args = list(), statistic.args = list(),
  cluster = NULL, debug = FALSE)
```

Arguments

data	a data frame containing the variables in the model.
statistic	a function or a character string (the name of a function) to be applied to each bootstrap replicate.
R	a positive integer, the number of bootstrap replicates.
m	a positive integer, the size of each bootstrap replicate.
sim	a character string indicating the type of simulation required. Possible values are "ordinary" (the default) and "parametric".
algorithm	a character string, the learning algorithm to be applied to the bootstrap replicates. Possible values are gs, iamb, fast.iamb, inter.iamb, mmpc, hc, tabu, mmhc and rsmax2. See bnlearn-package and documentation of each algorithm for details.
algorithm.args	a list of extra arguments to be passed to the learning algorithm.
statistic.args	a list of extra arguments to be passed to the function specified by statistic.
cluster	an optional cluster object from package **parallel**. See parallel integration for details and a simple example.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The first argument of statistic is the bn object encoding the network structure learned from the bootstrap sample; the arguments specified in statistics.args are extracted from the list and passed to statitstics as the 2nd, 3rd, etc. arguments.

Value

A list containing the results of the calls to statistic.

Examples

```
## Not run:
data(learning.test)
bn.boot(data = learning.test, R = 2, m = 500, algorithm = "gs",
  statistic = arcs)

## End(Not run)
```

---

bn.cv *Cross-validation for Bayesian networks*

Description

Perform a k-fold cross-validation for a learning algorithm or a fixed network structure.

Usage

```
bn.cv(data, bn, loss = NULL, k = 10, algorithm.args = list(),
  loss.args = list(), fit = "mle", fit.args = list(),
  cluster = NULL, debug = FALSE)
```

Arguments

data	a data frame containing the variables in the model.
bn	either a character string (the label of the learning algorithm to be applied to the training data in each iteration) or an object of class bn (a fixed network structure).
loss	a character string, the label of a loss function. If none is specified, the default loss function is the *Classification Error* for Bayesian networks classifiers; otherwise, the *Log-Likelihood Loss* for both discrete and continuous data sets. See below for additional details.
k	a positive integer number, the number of groups into which the data will be split.
algorithm.args	a list of extra arguments to be passed to the learning algorithm.
loss.args	a list of extra arguments to be passed to the loss function specified by loss.
fit	a character string, the label of the method used to fit the parameters of the newtork. See bn.fit for details.
fit.args	additional arguments for the parameter estimation prcoedure, see again bn.fit for details..
cluster	an optional cluster object from package **parallel**. See parallel integration for details and a simple example.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The following loss functions are implemented:

- *Log-Likelihood Loss* (`logl`): also known as *negative entropy* or *negentropy*, it is the negated expected log-likelihood of the test set for the Bayesian network fitted from the training set.
- *Gaussian Log-Likelihood Loss* (`logl-g`): the negated expected log-likelihood for Gaussian Bayesian networks.
- *Classification Error* (`pred`): the *prediction error* for a single node (specified by the `target` parameter in `loss.args`) in a discrete network.
- *Predictive Correlation* (`cor`): the *correlation* between the observed and the predicted values for a single node (specified by the `target` parameter in `loss.args`) in a Gaussian Bayesian network.
- *Mean Squared Error* (`mse`): the *mean squared error* between the observed and the predicted values for a single node (specified by the `target` parameter in `loss.args`) in a Gaussian Bayesian network.

Value

An object of class `bn.kcv`.

bn.cv(gaussian.test, 'mmhc')
```

bn.fit *Fit the parameters of a Bayesian network*

Description

Fit the parameters of a Bayesian network conditional on its structure.

Usage

```
bn.fit(x, data, method = "mle", ..., debug = FALSE)
custom.fit(x, dist, ordinal)
bn.net(x, debug = FALSE)
```

Arguments

x	an object of class bn (for bn.fit and custom.fit) or an object of class bn.fit (for bn.net).
data	a data frame containing the variables in the model.
dist	a named list, with element for each node of x. See below.
method	a character string, either mle for *Maximum Likelihood parameter estimation* or bayes for *Bayesian parameter estimation* (currently implemented only for discrete data).
...	additional arguments for the parameter estimation prcoedure, see below.
ordinal	a vector of character strings, the labels of the discrete nodes which should be saved as ordinal random variables (bn.fit.onode) instead of unordered factors (bn.fit.dnode).
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

bn.fit fits the parameters of a Bayesian network given its structure and a data set; bn.net returns the structure underlying a fitted Bayesian network.

An in-place replacement method is available to change the parameters of each node in a bn.fit object; see the examples for discrete, continuous and hybrid networks below. For a discrete node (class bn.fit.dnode or bn.fit.onode), the new parameters must be in a table object. For a Gaussian node (class bn.fit.gnode), the new parameters can be defined either by an lm, glm or pensim object (the latter is from the penalized package) or in a list with elements named coef, sd and optionally fitted and resid. For a conditional Gaussian node (class bn.fit.cgnode), the new parameters can be defined by a list with elements named coef, sd and optionally fitted, resid and configs. In both cases coef should contain the new regression coefficients, sd the standard deviation of the residuals, fitted the fitted values and resid the residuals. configs should contain the configurations if the discrete parents of the conditional Gaussian node, stored as a factor.

custom.fit takes a set of user-specified distributions and their parameters and uses them to build a bn.fit object. Its purpose is to specify a Bayesian network (complete with the parameters, not

only the structure) using knowledge from experts in the field instead of learning it from a data set. The distributions must be passed to the function in a list, with elements named after the nodes of the network structure `x`. Each element of the list must be in one of the formats described above for in-place replacement.

Value

`bn.fit` returns an object of class `bn.fit`, `bn.net` an object of class `bn`. See `bn class` and `bn.fit class` for details.

Note

Due to the way Bayesian networks are defined it is possible to estimate their parameters only if the network structure is completely directed (i.e. there are no undirected arcs). See `set.arc` and `pdag2dag` for two ways of manually setting the direction of one or more arcs.

The only supported additional parameter is the imaginary sample size (`iss`) for the Dirichlet posterior distribution of discrete networks (see `score` for details).

Examples

```
data(learning.test)

# learn the network structure.
res = gs(learning.test)
# set the direction of the only undirected arc, A - B.
res = set.arc(res, "A", "B")
# estimate the parameters of the Bayesian network.
fitted = bn.fit(res, learning.test)
# replace the parameters of the node B.
new.cpt = matrix(c(0.1, 0.2, 0.3, 0.2, 0.5, 0.6, 0.7, 0.3, 0.1),
            byrow = TRUE, ncol = 3,
            dimnames = list(B = c("a", "b", "c"), A = c("a", "b", "c")))
fitted$B = as.table(new.cpt)
# the network structure is still the same.
all.equal(res, bn.net(fitted))

# learn the network structure.
res = hc(gaussian.test)
# estimate the parameters of the Bayesian network.
fitted = bn.fit(res, gaussian.test)
# replace the parameters of the node F.
fitted$F = list(coef = c(1, 2, 3, 4, 5), sd = 3)
# set again the original parameters
```

```
fitted$F = lm(F ~ A + D + E + G, data = gaussian.test)

# discrete Bayesian network from expert knowledge.
net = model2network("[A][B][C|A:B]")
cptA = matrix(c(0.4, 0.6), ncol = 2, dimnames = list(NULL, c("LOW", "HIGH")))
cptB = matrix(c(0.8, 0.2), ncol = 2, dimnames = list(NULL, c("GOOD", "BAD")))
cptC = c(0.5, 0.5, 0.4, 0.6, 0.3, 0.7, 0.2, 0.8)
dim(cptC) = c(2, 2, 2)
dimnames(cptC) = list("C" = c("TRUE", "FALSE"), "A" =  c("LOW", "HIGH"),
                  "B" = c("GOOD", "BAD"))
cfit = custom.fit(net, dist = list(A = cptA, B = cptB, C = cptC))
# for ordinal nodes it is nearly the same.
cfit = custom.fit(net, dist = list(A = cptA, B = cptB, C = cptC),
         ordinal = c("A", "B"))

# Gaussian Bayesian network from expert knowledge.
distA = list(coef = c("(Intercept)" = 2), sd = 1)
distB = list(coef = c("(Intercept)" = 1), sd = 1.5)
distC = list(coef = c("(Intercept)" = 0.5, "A" = 0.75, "B" = 1.32), sd = 0.4)
cfit = custom.fit(net, dist = list(A = distA, B = distB, C = distC))

# conditional Gaussian Bayesian network from expert knowledge.
cptA = matrix(c(0.4, 0.6), ncol = 2, dimnames = list(NULL, c("LOW", "HIGH")))
distB = list(coef = c("(Intercept)" = 1), sd = 1.5)
distC = list(coef = matrix(c(1.2, 2.3, 3.4, 4.5), ncol = 2,
               dimnames = list(c("(Intercept)", "B"), NULL)),
          sd = c(0.3, 0.6))
cgfit = custom.fit(net, dist = list(A = cptA, B = distB, C = distC))
```

`bn.fit class` *The bn.fit class structure*

Description

The structure of an object of S3 class `bn.fit`.

Details

An object of class `bn.fit` is a list whose elements correspond to the nodes of the Bayesian network. If the latter is discrete (i.e. the nodes are multinomial random variables), the object also has class `bn.fit.dnet`; each node has class `bn.fit.dnode` and contains the following elements:

- `node`: a character string, the label of the node.
- `parents`: a vector of character strings, the labels of the parents of the node.
- `children`: a vector of character strings, the labels of the children of the node.
- `prob`: a (multi)dimensional numeric table, the conditional probability table of the node given its parents.

Nodes encoding ordinal variables (i.e. ordered factors) have class `bn.fit.onode` and contain the same elements as `bn.fit.dnode` nodes. Networks containing only ordinal nodes also have class `bn.fit.onet`, while those contatining both ordinal and multinomial nodes also have class `bn.fit.donet`.

If on the other hand the network is continuous (i.e. the nodes are Gaussian random variables), the object also has class `bn.fit.gnet`; each node has class `bn.fit.gnode` and contains the following elements:

- `node`: a character string, the label of the node.
- `parents`: a vector of character strings, the labels of the parents of the node.
- `children`: a vector of character strings, the labels of the children of the node.
- `coefficients`: a numeric vector, the linear regression coefficients of the parents against the node.
- `residuals`: a numeric vector, the residuals of the linear regression.
- `fitted.values`: a numeric vector, the fitted mean values of the linear regression.
- `sd`: a numeric value, the standard deviation of the residuals (i.e. the standard error).

Hybrid (i.e. conditional linear Gaussian) networks also have class `bn.fit.gnet`. Gaussian nodes have class `bn.fit.gnode`, discrete nodes have class `bn.fit.dnode` and conditional Gaussian nodes have class `bn.fit.cgnode`. Each node contains the following elements:

- `node`: a character string, the label of the node.
- `parents`: a vector of character strings, the labels of the parents of the node.
- `children`: a vector of character strings, the labels of the children of the node.
- `dparents`: an integer vector, the indexes of the discrete parents in `parents`.
- `gparents`: an integer vector, the indexes of the continuous parents in `parents`.
- `dlevels`: a list containing the levels of the discrete parents in `parents`.
- `coefficients`: a numeric matrix, the linear regression coefficients of the continuous parents. Each column corresponds to a configuration of the discrete parents.
- `residuals`: a numeric vector, the residuals of the linear regression.
- `fitted.values`: a numeric vector, the fitted mean values of the linear regression.
- `configs`: an integer vector, the indexes of the configurations of the discrete parents.
- `sd`: a numeric vector, the standard deviation of the residuals (i.e. the standard error) for each configuration of the discrete parents.

Furthermore, Bayesian network classifiers store the label of the training node in an additional attribute named `training`.

Author(s)

Marco Scutari

bn.fit plots *Plot fitted Bayesian networks*

Description

Plot functions for the bn.fit, bn.fit.dnode and bn.fit.gnode classes, based on the **lattice** package.

Usage

```
## for Gaussian Bayesian networks.
bn.fit.qqplot(fitted, xlab = "Theoretical Quantiles",
  ylab = "Sample Quantiles", main = "Normal Q-Q Plot", ...)
bn.fit.histogram(fitted, density = TRUE, xlab = "Residuals",
  ylab = ifelse(density, "Density", ""),
  main = "Histogram of the residuals", ...)
bn.fit.xyplot(fitted, xlab = "Fitted values",
  ylab = "Residuals", main = "Residuals vs Fitted", ...)
## for discrete (multinomial and ordinal) Bayesian networks.
bn.fit.barchart(fitted, xlab = "Probabilities",
  ylab = "Levels", main = "Conditional Probabilities", ...)
bn.fit.dotplot(fitted, xlab = "Probabilities",
  ylab = "Levels", main = "Conditional Probabilities", ...)
```

Arguments

fitted	an object of class bn.fit, bn.fit.dnode or bn.fit.gnode.
xlab, ylab, main	the label of the x axis, of the y axis, and the plot title.
density	a boolean value. If TRUE the histogram is plotted using relative frequencies, and the matching normal density is added to the plot.
...	additional arguments to be passed to **lattice** functions.

Details

bn.fit.qqplot draws a quantile-quantile plot of the residuals.

bn.fit.histogram draws a histogram of the residuals, using either absolute or relative frequencies.

bn.fit.xyplot plots the residuals versus the fitted values.

bn.fit.barchart and bn.fit.dotplot plot the probabilities in the conditional probability table associated with each node.

Value

The **lattice** plot objects. Note that if auto-printing is turned off (for example when the code is loaded with the source function), the return value must be printed explicitly for the plot to be displayed.

bn.fit utilities *Utilities to manipulate fitted Bayesian networks*

Description

Assign, extract or compute various quantities of interest from an object of class bn.fit, bn.fit.dnode, bn.fit.gnode or bn.fit.onode.

Usage

```
## methods available for "bn.fit"
## S3 method for class 'bn.fit'
fitted(object, ...)
## S3 method for class 'bn.fit'
coef(object, ...)
## S3 method for class 'bn.fit'
residuals(object, ...)
## S3 method for class 'bn.fit'
predict(object, node, data, method = "parents", ..., debug = FALSE)
## S3 method for class 'bn.fit'
logLik(object, data, nodes, by.sample = FALSE, ...)
## S3 method for class 'bn.fit'
AIC(object, data, ..., k = 1)
## S3 method for class 'bn.fit'
BIC(object, data, ...)

## methods available for "bn.fit.dnode"
## S3 method for class 'bn.fit.dnode'
coef(object, ...)
## S3 method for class 'bn.fit.dnode'
predict(object, data, ..., debug = FALSE)

## methods available for "bn.fit.onode"
## S3 method for class 'bn.fit.onode'
coef(object, ...)
## S3 method for class 'bn.fit.onode'
predict(object, data, ..., debug = FALSE)

## methods available for "bn.fit.gnode"
## S3 method for class 'bn.fit.gnode'
```

```
fitted(object, ...)
## S3 method for class 'bn.fit.gnode'
coef(object, ...)
## S3 method for class 'bn.fit.gnode'
residuals(object, ...)
## S3 method for class 'bn.fit.gnode'
predict(object, data, ..., debug = FALSE)
```

Arguments

object	an object of class bn.fit, bn.fit.dnode or bn.fit.gnode.
node	a character string, the label of a node.
nodes	a vector of character strings, the label of a nodes whose loglikelihood components are to be computed.
data	a data frame containing the variables in the model.
method	a character sting, the method used to estimate predictions. See below.
...	additional arguments. See below.
k	a numeric value, the penalty per parameter to be used; the default k = 1 gives the expression used to compute AIC.
by.sample	a boolean value. If TRUE, logLik returns a vector containing the the log-likelihood of each observations in the sample. If FALSE, logLik returns a single value, the likelihood of the whole sample.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

coef (and its alias coefficients) extracts model coefficients (which are conditional probabilities in discrete networks and linear regression coefficients in Gaussian networks).

residuals (and its alias resid) extracts model residuals and fitted (and its alias fitted.values) extracts fitted values from fitted Gaussian networks. If the bn.fit object does not include the residuals or the fitted values (for the nodes of interest, in the case of bn.fit.gnode objects), both functions return NULL.

predict returns the predicted values for node given the data specified by data. Depending on the value of method, the predicted values are computed as follows.

- parents: the predicted values are computed by plugging in the new values for the parents of node in the local probability distribution of node extracted from fitted.
- bayes-lw: the predicted values are computed by averaging likelihood weighting simulations performed using all the available nodes as evidence (obviously, with the exception of the node whose values we are predicting). The number of random samples which are averaged for each new observation is controlled by the n optional argument; the default is 500. If the variable being predicted is discrete, the predicted level is that with the highest conditional probability. If the variable is continuous, the predicted value is the expected value of the conditional distribution.

Both methods are available for bn.fit objects; predictions for bn.fit.dnode, bn.fit.onode and bn.fit.gnode objects can only be estimated with method = "parents". That is the default method for bn.fit objects as well.

Value

predict returns a numeric vector (for Gaussian networks) or a factor (for discrete networks).

logLik returns a numeric vector or a single numeric value, depending on the value of by.sample. AIC and BIC always return a single numeric value.

All the other functions return a list with an element for each node in the network (if object has class bn.fit) or a numeric vector (if object has class bn.fit.dnode or bn.fit.gnode).

Note

Ties in prediction are broken using *Bayesian tie breaking*, i.e. sampling at random from the tied values. Therefore, setting the random seed is required to get reproducible results.

predict accepts either a bn or a bn.fit object as its first argument. For the former, the parameters of the network are fitted on data, that is, the observations whose class labels the function is trying to predict.

str(residuals(fitted))

data(learning.test)
res2 = hc(learning.test)
fitted2 = bn.fit(res2, learning.test)
coefficients(fitted2$E)
```

bn.kcv class *The bn.kcv class structure*

Description

The structure of an object of S3 class bn.kcv.

Details

An object of class bn.kcv is a list whose elements correspond to the iterations of a k-fold cross-validation. Each element contains the following objects:

- test: an integer vector, the indexes of the observations used as a test set.
- fitted: an object of class bn.fit, the Bayesian network fitted from the training set.
- loss: the value of the loss function.

If the loss function requires to predict values from the test sets, each element also contains:

- predicted: a factor or a numeric vector, the predicted values for the target node in the test set.
- observed: a factor or a numeric vector, the observed values for the target node in the test set.

In addition, an object of class bn.kcv has the following attributes:

- loss: a character string, the label of the loss function.
- mean: the mean of the values of the loss function computed in the k iterations of the cross-validation.
- bn: either a character string (the label of the learning algorithm to be applied to the training data in each iteration) or an object of class bn (a fixed network structure).

Author(s)

Marco Scutari

bn.strength class — *The bn.strength class structure*

Description

The structure of an object of S3 class bn.strength.

Details

An object of class bn.strength is a data frame with the following columns (one row for each arc):

- from, to: the nodes incident on the arc.
- strength: the strength of the arc. See arc.strength, boot.strength, custom.strength and strength.plot for details.

and some additional attributes:

- mode: a character string, the criterion used to compute the strength coefficient. It can be equal to test, score or bootstrap.
- threshold: a numeric value, the threshold used to determine if a strength coefficient is significant.

An optional column called direction may also be present, giving the probability of the direction of an arc given its presence in the graph.

Only the plot method is defined for this class; therefore, it can be manipulated as a standard data frame.

Author(s)

Marco Scutari

bn.var — *Structure variability of Bayesian networks*

Description

Measure the variability of the structure of a Bayesian network.

Usage

```
# first and second moments' estimation
bn.moments(data, R = 200, m = nrow(data), algorithm,
  algorithm.args = list(), reduce = NULL, debug = FALSE)
# descriptive statistics
bn.var(x, method)
```

Arguments

data	a data frame containing the variables in the model.
R	a positive integer, the number of bootstrap replicates (in bn.moments) or the number of Monte Carlo samples (in bn.var.test).
m	a positive integer, the bootstrap sample size.
algorithm	a character string, the learning algorithm to be applied to the bootstrap replicates. Possible values are gs, iamb, fast.iamb, inter.iamb, mmpc, hc, tabu, mmhc and rsmax2. See bnlearn-package and the documentation of each algorithm for details.
algorithm.args	a list of extra arguments to be passed to the learning algorithm.
x	a covariance matrix or an object of class mvber.moments (the return value of the bn.moments function).
method	a character string, the label of the statistic. Possible values are tvar (*total variance*), gvar (generalized variance), nvar (*Frobenius matrix norm*, which is equivalent to *Nagao's test*) and nvark (another measure based on the *Frobenius matrix norm*).
reduce	a character string, either first or second. If first all the arcs with first moment equal to zero are dropped; if if second all the arcs with zero variance are dropped.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

bn.moments returns an object of class mvber.moments.

bn.var returns a vector of two elements, the observed value of the statistic (named statistic) and its normalized equivalent (named normalized).

Note

These functions are experimental implementations of techniques still in development; their form (name, parameters, etc.) will likely change without notice in the future.

z =  bn.moments(learning.test, algorithm = "gs", R = 100)
bn.var(z, method = "tvar")

## End(Not run)
```

`choose.direction` *Try to infer the direction of an undirected arc*

Description

Check both possible directed arcs for existence, and choose the one with the lowest p-value, the highest score or the highest bootstrap probability.

Usage

```
choose.direction(x, arc, data, criterion = NULL, ..., debug = FALSE)
```

Arguments

`x`	an object of class `bn`.
`arc`	a character string vector of length 2, the labels of two nodes of the graph.
`data`	a data frame containing the data the Bayesian network was learned from.
`criterion`	a character string, the label of a score function, the label of an independence test or `bootstrap`. See `bnlearn-package` for details on the first two possibilities.
`...`	additional tuning parameters for the network score. See `score` for details.
`debug`	a boolean value. If `TRUE` a lot of debugging output is printed; otherwise the function is completely silent.

Details

If `criterion` is `bootstrap`, `choose.directions` accepts the same arguments as `boot.strength`: `R` (the number of bootstrap replicates), `m` (the bootstrap sample size), `algorithm` (the structure learning algorithm), `algorithm.args` (the arguments to pass to the structure learning algorithm) and `cpdag` (whether to transform the network structure to the CPDAG representation of the equivalence class it belongs to).

Value

`choose.direction` returns invisibly an updated copy of `x`.

score, arc.strength.

Examples

```
data(learning.test)
res = gs(learning.test)

## the arc A - B has no direction.
choose.direction(res, learning.test, arc = c("A", "B"), debug = TRUE)

## let's see score equivalence in action.
choose.direction(res, learning.test, criterion = "aic",
  arc = c("A", "B"), debug = TRUE)

## arcs which introduce cycles are handled correctly.
res = set.arc(res, "A", "B")
# now A -> B -> E -> A is a cycle.
choose.direction(res, learning.test, arc = c("E", "A"), debug = TRUE)

## Not run:
choose.direction(res, learning.test, arc = c("D", "E"), criterion = "bootstrap",
  R = 100, algorithm = "iamb", algorithm.args = list(test = "x2"), cpdag = TRUE,
  debug = TRUE)

## End(Not run)
```

---

ci.test *Independence and Conditional Independence Tests*

Description

Perform either an independence test or a conditional independence test.

Usage

```
ci.test(x, y, z, data, test, B, debug = FALSE)
```

Arguments

x	a character string (the name of a variable), a data frame, a numeric vector or a factor object.
y	a character string (the name of another variable), a numeric vector or a factor object.
z	a vector of character strings (the names of the conditioning variables), a numeric vector, a factor object or a data frame. If NULL an independence test will be executed.
data	a data frame containing the variables to be tested.

test	a character string, the label of the conditional independence test to be used in the algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See bnlearn-package for details.
B	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the test argument is not a permutation test.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

An object of class htest containing the following components:

statistic	the value the test statistic.
parameter	the degrees of freedom of the approximate chi-squared or t distribution of the test statistic; the number of permutationscomputed by Monte Carlo tests. Semiparametric tests have both.
p.value	the p-value for the test.
method	a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
data.name	a character string giving the name(s) of the data.
null.value	the value of the test statistic under the null hypothesis, always 0.
alternative	a character string describing the alternative hypothesis

---

clgaussian.test *Synthetic (mixed) data set to test learning algorithms*

Description

This a synthetic data set used as a test case in the **bnlearn** package.

Usage

```
data(gaussian.test)
```

Format

The clgaussian.test data set contains one normal (Gaussian) variable, 4 discrete variables and 3 conditional Gaussian variables.

Note

The R script to generate data from this network is shipped in the 'network.scripts' directory of this package.

Examples

```
# load the data and build the correct network from the model string.
data(clgaussian.test)
res = empty.graph(names(clgaussian.test))
modelstring(res) = "[A][B][C][H][D|A:H][F|B:C][E|B:D][G|A:D:E:F]"
plot(res)
```

compare *Compare two different Bayesian networks*

Description

Compare two different Bayesian networks; compute the Structural Hamming Distance (SHD) between them or the Hamming distance between their skeletons.

Usage

```
compare(target, current, arcs = FALSE)
## S3 method for class 'bn'
all.equal(target, current, ...)

shd(learned, true, debug = FALSE)
hamming(learned, true, debug = FALSE)
```

Arguments

target, learned	an object of class bn.
current, true	another object of class bn.
...	extra arguments from the generic method (currently ignored).
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.
arcs	a boolean value. See below.

Value

compare returns a list containing the number of true positives (tp, the number of arcs in current also present in target), of false positives (fp, the number of arcs in current not present in target) and of false negatives (tn, the number of arcs not in current but present in target) if arcs is FALSE; or the corresponding arc sets if arcs is TRUE.

all.equal returns either TRUE or a character string describing the differences between target and current.

shd and hamming return a non-negative integer number.

constraint-based algorithms

Constraint-based structure learning algorithms

Description

Learn the equivalence class of a directed acyclic graph (DAG) from data using the Grow-Shrink (GS), the Incremental Association (IAMB), the Fast Incremental Association (Fast IAMB) or the Interleaved Incremental Association (Inter IAMB) constraint-based algorithms. Also use the same algorithms to learn the Markov blanket of a single variable.

Usage

```
gs(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE,
  undirected = FALSE)
iamb(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE,
  undirected = FALSE)
fast.iamb(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE,
  undirected = FALSE)
inter.iamb(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE,
  undirected = FALSE)
```

Arguments

x	a data frame containing the variables in the model.
cluster	an optional cluster object from package **parallel**. See parallel integration for details and a simple example.
whitelist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs to be included in the graph.
blacklist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs not to be included in the graph.

`test`	a character string, the label of the conditional independence test to be used in the algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See `bnlearn-package` for details.
`alpha`	a numeric value, the target nominal type I error rate.
`B`	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the `test` argument is not a permutation test.
`debug`	a boolean value. If `TRUE` a lot of debugging output is printed; otherwise the function is completely silent.
`optimized`	a boolean value. See `bnlearn-package` for details.
`strict`	a boolean value. If `TRUE` conflicting results in the learning process generate an error; otherwise they result in a warning.
`undirected`	a boolean value. If `TRUE` no attempt will be made to determine the orientation of the arcs; the returned (undirected) graph will represent the underlying structure of the Bayesian network.

Value

An object of class `bn`. See `bn-class` for details.

coronary *Coronary Heart Disease data set*

Description

Probable risk factors for coronary trombosis, comprising data from 1841 men.

Usage

```
data(coronary)
```

Format

The coronary data set contains the following 6 variables:

- Smoking (*smoking*): a two-level factor with levels no and yes.
- M. Work (*strenuous mental work*): a two-level factor with levels no and yes.
- P. Work (*strenuous physical work*): a two-level factor with levels no and yes.
- Pressure (*systolic blood pressure*): a two-level factor with levels <140 and >140.
- Proteins (*ratio of beta and alpha lipoproteins*): a two-level factor with levels <3 and >3.
- Family (*family anamnesis of coronary heart disease*): a two-level factor with levels neg and pos.

cpdag *Equivalence classes, moral graphs and consistent extensions*

Description

Find the equivalence class and the v-structures of a Bayesian network, construct its moral graph, or create a consistent extension of an equivalent class.

Usage

```
cpdag(x, moral = TRUE, debug = FALSE)
cextend(x, strict = TRUE, debug = FALSE)
vstructs(x, arcs = FALSE, moral = TRUE, debug = FALSE)
moral(x, debug = FALSE)
```

Arguments

x	an object of class bn.
arcs	a boolean value. If TRUE the arcs that are part of at least one v-structure are returned instead of the v-structures themselves.
moral	a boolean value. If TRUE we define a v-structure as in Pearl (2000); if FALSE, as in Koller and Friedman (2009). See below.
strict	a boolean value. If no consistent extension is possible and strict is TRUE, an error is generated; otherwise a partially extended graph is returned with a warning.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

What kind of arc configuration is called a v-structure is not uniquely defined in literature. The original definition from Pearl (2000), which is still followed by most texts and papers, states that the two parents in the v-structure must not be connected by an arc. However, Koller and Friedman (2009) call that a *immoral v-structure* and call a *moral v-structure* a v-structure in which the parents are linked by an arc. This mirrors the *unshielded* versus *shielded collider* naming convention, but is confusing.

Setting moral to FALSE in cpdag and vstructs makes those functions follow the definition from Koller and Friedman (2009); the default value of TRUE, on the other hand, makes those functions follow the definition from Pearl (2000). The former call *v-structures* both shielded and unshielded colliders (respectively *moral v-structures* and *immoral v-structures*); the latter requires v-structures to be unshielded colliders.

Value

cpdag returns an object of class bn, representing the equivalence class. moral on the other hand returns the moral graph. See bn-class for details.

cextend returns an object of class bn, representing a DAG that is the consistent extension of x.

vstructs returns a matrix with either 2 or 3 columns, according to the value of the arcs parameter.

vstructs(res)
```

---

cpquery *Perform conditional probability queries*

Description

Perform conditional probability queries (CPQs).

Usage

```
cpquery(fitted, event, evidence, cluster = NULL, method = "ls", ...,
  debug = FALSE)
cpdist(fitted, nodes, evidence, cluster = NULL, method = "ls", ...,
  debug = FALSE)

mutilated(x, evidence)
```

Arguments

`fitted`	an object of class `bn.fit`.
`x`	an object of class `bn` or `bn.fit`.
`event, evidence`	see below.
`nodes`	a vector of character strings, the labels of the nodes whose conditional distribution we are interested in.
`cluster`	an optional cluster object from package **parallel**. See `parallel integration` for details and a simple example.
`method`	a character string, the method used to perform the conditional probability query. Currently only *logic sampling* (`ls`, the default) and *likelihood weighting* (`lw`) are implemented.
`...`	additional tuning parameters.
`debug`	a boolean value. If `TRUE` a lot of debugging output is printed; otherwise the function is completely silent.

Details

`cpquery` estimates the conditional probability of `event` given `evidence` using the method specified in the `method` argument.

`cpdist` generates random observations conditional on the `evidence` using the method specified in the `method` argument.

`mutilated` constructs the mutilated network used for sampling in *likelihood weighting*.

Value

`cpquery` returns a numeric value, the conditional probability of `event` conditional on `evidence`.

`cpudist` returns a data frame containing the observations generated from the conditional distribution of the `nodes` conditional on `evidence`. The data frame has class `c("bn.cpdist", "data.frame")`, and a `method` attribute storing the value of the `method` argument. In the case of likelihood weighting, the weights are also attached as an attribute called `weights`.

`mutilated` returns a `bn` or `bn.fit` object, depending on the class of `x`.

Logic Sampling

The `event` and `evidence` arguments must be two expressions describing the event of interest and the conditioning evidence in a format such that, if we denote with `data` the data set the network was learned from, `data[evidence, ]` and `data[event, ]` return the correct observations. If either `event` or `evidence` is set to `TRUE` an unconditional probability query is performed with respect to that argument.

Three tuning parameters are available:

- `n`: a positive integer number, the number of random observations to generate from `fitted`. Defaults to `5000 * log10(nparams.fitted(fitted))` for discrete networks and `500 * nparams.fitted(fitted)` for Gaussian networks.

- batch: a positive integer number, the size of each batch of random observations. Defaults to 10^4.
- query.nodes: a a vector of character strings, the labels of the nodes involved in event and evidence. Simple queries do not require to generate observations from all the nodes in the network, so cpquery and cpdist try to identify which nodes are used in event and evidence and reduce the network to their upper closure. query.nodes may be used to manually specify these nodes when automatic identification fails; there is no reason to use it otherwise.

Note that the number of observations returned by cpdist is always smaller than n, because logic sampling is a form of rejection sampling. Therefore, only the obervations matching evidence (out of the n that are generated) are returned, and their number depends on the probability of evidence.

Likelihood Weighting

The event argument must be an expression describing the event of interest, as in logic sampling. The evidence argument must be a named list:

- Each element corresponds to one node in the network and must contain the value that node will be set to when sampling.
- In the case of a continuous node, two values can also be provided. In that case, the value for that node will be sampled from a uniform distribution on the interval delimited by the specified values.
- In the case of a discrete or ordinal node, two or more values can also be provided. In that case, the value for that node will be sampled with uniform probability from the set of specified values.

If either event or evidence is set to TRUE an unconditional probability query is performed with respect to that argument.

Tuning parameters are the same as for logic sampling: n, batch and query.nodes.

Note that the observations returned by cpdist are generated from the mutilated network, and need to be weighted appropriately when computing summary statistics (for more details, see the references below). cpquery does that automatically when computing the final conditional probability. Also note that the batch argument is ignored in cpdist for speed and memory efficiency.

References

Koller D, Friedman N (2009). *Probabilistic Graphical Models: Principles and Techniques*. MIT Press.

Korb K, Nicholson AE (2010). *Bayesian Artificial Intelligence*. Chapman & Hall/CRC, 2nd edition.

Examples

```
## discrete Bayesian network (it is the same with ordinal nodes).
data(learning.test)
fitted = bn.fit(hc(learning.test), learning.test)
# the result should be around 0.025.
cpquery(fitted, (B == "b"), (A == "a"))
# for a single observation, predict the value of a single
# variable conditional on the others.
var = names(learning.test)
obs = 2
str = paste("(", names(learning.test)[-3], "=='",
        sapply(learning.test[obs,-3], as.character), "')",
        sep = "", collapse = " & ")
str
str2 = paste("(", names(learning.test)[3], "=='",
         as.character(learning.test[obs, 3]), "')", sep = "")
str2
cpquery(fitted, eval(parse(text = str2)), eval(parse(text = str)))
# do the same with likelihood weighting
cpquery(fitted, event = eval(parse(text = str2)),
  evidence = as.list(learning.test[2, -3]), method = "lw")
# conditional distribution of A given C == "c".
table(cpdist(fitted, "A", (C == "c")))

## Gaussian Bayesian network.
data(gaussian.test)
fitted = bn.fit(hc(gaussian.test), gaussian.test)
# the result should be around 0.04.
cpquery(fitted,
  event = ((A >= 0) & (A <= 1)) & ((B >= 0) & (B <= 3)),
  evidence = (C + D < 10))
```

`deal integration` *bnlearn - deal package integration*

Description

How to use the **bnlearn** package with the Bayesian network learning methods provided by the **deal** package.

Export a bn object to deal

```
# load the bnlearn package.
> library(bnlearn)
> data(learning.test)
# learn the network structure.
> res = hc(learning.test)
> modelstring(res)
[1] "[A][C][F][B|A][D|A:C][E|B:F]"
```

```
# load the deal package.
> library(deal)

Attaching package: 'deal'

        The following object(s) are masked from package:bnlearn :

         modelstring,
         nodes,
         score

> bnlearn::node.ordering(res)
[1] "A" "C" "F" "B" "D" "E"
# create an empty network object.
> net = deal::network(learning.test[, node.ordering(res)])
# convert the bn object via its string representation.
> net = deal::as.network(bnlearn::modelstring(res), net)
# the network is the same, modulo some differences due to the
# partial ordering of the nodes.
> deal::modelstring(net)
[1] "[A][C][F][B|A][D|A:C][E|F:B]"
> bnlearn::modelstring(res)
[1] "[A][C][F][B|A][D|A:C][E|B:F]"
```

Import a network structure from deal

```
res2 = bnlearn::model2network(deal::modelstring(net))
```

Author(s)

Marco Scutari

---

dsep *Test d-separation*

Description

Check whether two nodes are d-separated.

Usage

```
dsep(bn, x, y, z)
```

Arguments

bn	an object of class bn.
x,y	a character string, the label of a node.
z	an optional vector of character strings, the label of the (candidate) d-separating nodes. It defaults to the empty set.

Value

dsep returns TRUE if x and y are d-separated by z, and FALSE otherwise.

Author(s)

Marco Scutari

References

Koller D, Friedman N (2009). *Probabilistic Graphical Models: Principles and Techniques*. MIT Press.

Examples

```
bn = model2network("[A][C|A][B|C]")
dsep(bn, "A", "B", "C")
bn = model2network("[A][C][B|A:C]")
dsep(bn, "A", "B", "C")
```

---

foreign files utilities

Read and write BIF, NET, DSC and DOT files

Description

Read networks saved from other programs into bn.fit objects, and dump bn and bn.fit objects into files for other programs to read.

Usage

```
# Old (non-XML) Bayesian Interchange format.
read.bif(file, debug = FALSE)
write.bif(file, fitted)

# Microsoft Interchange format.
read.dsc(file, debug = FALSE)
write.dsc(file, fitted)

# HUGIN flat network format.
read.net(file, debug = FALSE)
```

```
write.net(file, fitted)

# Graphviz DOT format.
write.dot(file, graph)
```

Arguments

file	a connection object or a character string.
fitted	an object of class bn.fit.
graph	an object of class bn or bn.fit.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

read.bif, read.dsc and read.net return an object of class bn.fit.

write.bif, write.dsc, write.net and write.dot return NULL invisibly.

Note

All the networks present in the Bayesian Network Repository have associated BIF, DSC and NET files that can be imported with read.bif, read.dsc and read.net.

HUGIN can import and export NET files; Netica can read (but not write) DSC files; and Genie can read and write both DSC and NET files.

DOT files can be read by Graphviz, Gephi and a variety of other programs.

Please note that these functions work on a "best effort" basis, as the parsing of these formats have been implementing by reverse engineering the file format from publicly available examples.

gaussian.test *Synthetic (continuous) data set to test learning algorithms*

Description

This a synthetic data set used as a test case in the **bnlearn** package.

Usage

```
data(gaussian.test)
```

Format

The `gaussian.test` data set contains seven normal (Gaussian) variables.

Note

The R script to generate data from this network is shipped in the '`network.scripts`' directory of this package.

Examples

```
# load the data and build the correct network from the model string.
data(gaussian.test)
res = empty.graph(names(gaussian.test))
modelstring(res) = "[A][B][E][G][C|A:B][D|B][F|A:D:E:G]"
plot(res)
```

gRain integration *Import and export networks from the gRain package*

Description

Convert `bn.fit` objects to `grain` objects and vice versa.

Usage

```
## S3 method for class 'grain'
as.bn.fit(x)
## S3 method for class 'bn.fit'
as.grain(x)
```

Arguments

`x`	an object of class `grain` (for `as.bn.fit`) or `bn.fit` (for `as.grain`).

Value

An object of class `grain` (for `as.grain`) or `bn.fit` (for `as.bn.fit`).

Note

Conditional probability tables in `grain` objects must be completely specified; on the other hand, `bn.fit` allows `NaN` values for unobserved parents' configurations. Such `bn.fit` objects will be converted to `grain` objects by replacing the missing conditional probability distributions with uniform distributions.

Another solution to this problem is to fit another `bn.fit` with `method = "bayes"` and a low `iss` value, using the same data and network structure.

Ordinal nodes will be treated as categorical by `as.grain`, disregarding the ordering of the levels.

Author(s)

Marco Scutari

Examples

```
## Not run:
library(gRain)
a = bn.fit(hc(learning.test), learning.test)
b = as.grain(a)
c = as.bn.fit(b)
## End(Not run)
```

---

graph generation utilities

Generate empty or random graphs

Description

Generate empty or random directed acyclic graphs from a given set of nodes.

Usage

```
empty.graph(nodes, num = 1)
random.graph(nodes, num = 1, method = "ordered", ..., debug = FALSE)
```

Arguments

`nodes`	a vector of character strings, the labels of the nodes.
`num`	an integer, the number of graphs to be generated.
`method`	a character string, the label of a score. Possible values are `ordered` (*full ordering* based generation), `ic-dag` (Ide's and Cozman's *Generating Multi-connected DAGs* algorithm), `melancon` (Melancon's and Philippe's *Uniform Random Acyclic Digraphs* algorithm) and `empty` (generates empty graphs).

...	additional tuning parameters (see below).
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent. Ignored in some generation methods.

Details

Available graph generation algorithms are:

- *full ordering* based generation (ordered): generates graphs whose node ordering is given by the order of the labels in the nodes parameter. The same algorithm is used in the randomDAG function in package **pcalg**.
- Ide's and Cozman's *Generating Multi-connected DAGs* algorithm (ic-dag): generates graphs with a uniform probability distribution over the set of multiconnected graphs.
- Melancon's and Philippe's *Uniform Random Acyclic Digraphs* algorithm (melancon): generates graphs with a uniform probability distribution over the set of all possible graphs.
- *empty graphs* (empty): generates graphs without any arc.

Additional parameters for the random.graph function are:

- prob: the probability of each arc to be present in a graph generated by the ordered algorithm. The default value is 2 / (length(nodes) - 1), which results in a sparse graph (the number of arcs should be of the same order as the number of nodes).
- burn.in: the number of iterations for the ic-dag and melancon algorithms to converge to a stationary (and uniform) probability distribution. The default value is 6 * length(nodes)^2.
- every: return only one graph every number of steps instead of all the graphs generated with ic-dag and melancon. Since both algorithms are based on Markov Chain Monte Carlo approaches, high values of every result in a more diverse set of networks. The default value is 1, i.e. to return all the networks that are generated.
- max.degree: the maximum degree for any node in a graph generated by the ic-dag and melancon algorithms. The default value is Inf.
- max.in.degree: the maximum in-degree for any node in a graph generated by the ic-dag and melancon algorithms. The default value is Inf.
- max.out.degree: the maximum out-degree for any node in a graph generated by the ic-dag and melancon algorithms. The default value is Inf.

Value

Both empty.graph and random.graph return an object of class bn (if num is equal to 1) or a list of objects of class bn (otherwise). If every is greated than 1, random.graph always returns a list, regardless of the number of graphs it contains.

Melancon G, Philippe F (2004). "Generating Connected Acyclic Digraphs Uniformly at Random". *Information Processing Letters*, **90**(4), 209-213.

Examples

```
empty.graph(LETTERS[1:8])
random.graph(LETTERS[1:8])
plot(random.graph(LETTERS[1:8], method = "ic-dag", max.in.degree = 2))
plot(random.graph(LETTERS[1:8]))
plot(random.graph(LETTERS[1:8], prob = 0.2))
```

---

graph integration *Import and export networks from the graph package*

Description

Convert bn and bn.fit objects to graphNEL and graphAM objects and vice versa.

Usage

```
## S3 method for class 'graphNEL'
as.bn(x)
## S3 method for class 'graphAM'
as.bn(x)
## S3 method for class 'bn'
as.graphNEL(x)
## S3 method for class 'bn.fit'
as.graphNEL(x)
## S3 method for class 'bn'
as.graphAM(x)
## S3 method for class 'bn.fit'
as.graphAM(x)
```

Arguments

x	an object of class bn, bn.fit, graphNEL, graphAM.

Value

An object of the relevant class.

Note

The corresponding S4 methods are exported as well, and are just wrappers around the S3 ones. So, for example, both `as.graphNEL(x)` and `as(x, "graphNEL")` work and return identical objects.

Author(s)

Marco Scutari

Examples

```
## Not run:
library(graph)
a = bn.fit(hc(learning.test), learning.test)
b = as.graphNEL(a)
c = as.bn(b)
## End(Not run)
```

---

graph utilities *Utilities to manipulate graphs*

Description

Check and manipulate graph-related properties of an object of class bn.

Usage

```
# check whether the graph is acyclic/completely directed.
acyclic(x, debug = FALSE)
directed(x)
# check whether there is a path between two nodes.
path(x, from, to, direct = TRUE, underlying.graph = FALSE, debug = FALSE)
# build the skeleton or a complete orientation of the graph.
skeleton(x)
pdag2dag(x, ordering)
# build a subgraph spanning a subset of nodes.
subgraph(x, nodes)
```

Arguments

x	an object of class bn. acyclic, directed and path also accept objects of class bn.fit.
from	a character string, the label of a node.
to	a character string, the label of a node (different from from).
direct	a boolean value. If FALSE ignore any arc between from and to when looking for a path.

underlying.graph
: a boolean value. If TRUE the underlying undirected graph is used instead of the (directed) one from the x parameter.

ordering
: the labels of all the nodes in the graph; their order is the node ordering used to set the direction of undirected arcs.

nodes
: the labels of the nodes that induce the subgraph.

debug
: a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

acyclic, path and directed return a boolean value.
skeleton, pdag2dag and subgraph return an object of class bn.

Author(s)

Marco Scutari

References

Bang-Jensen J, Gutin G (2009). *Digraphs: Theory, Algorithms and Applications*. Springer, 2nd edition.

Examples

```
data(learning.test)
res = gs(learning.test)

acyclic(res)
directed(res)
res = pdag2dag(res, ordering = LETTERS[1:6])
res
directed(res)
skeleton(res)
```

---

graphviz.plot *Advanced Bayesian network plots*

Description

Plot the graph associated with a Bayesian network using the **Rgraphviz** package.

Usage

```
graphviz.plot(x, highlight = NULL, layout = "dot",
  shape = "circle", main = NULL, sub = NULL)
```

Arguments

x	an object of class bn or bn.fit.
highlight	a list, see below.
layout	a character string, the layout parameter to be passed to **Rgraphviz**. Possible values are dots, neato, twopi, circo and fdp. See **Rgraphviz** documentation for details.
shape	a character string, the shape of the nodes. Can be circle, ellipse or rectangle.
main	a character string, the main title of the graph. It's plotted at the top of the graph.
sub	a character string, a subtitle which is plotted at the bottom of the graph.

Details

The highlight parameter is a list with at least one of the following elements:

- nodes: a character vector, the labels of the nodes to be highlighted.
- arcs: the arcs to be highlighted (a two-column matrix, whose columns are labeled from and to).

and optionally one or more of the following formatting parameters:

- col: an integer or character string (the highlight colour for the arcs and the node frames). The default value is red.
- textCol: an integer or character string (the highlight colour for the labels of the nodes). The default value is black.
- fill: an integer or character string (the colour used as a background colour for the nodes). The default value is white.
- lwd: a positive number (the line width of highlighted arcs). It overrides the line width settings in strength.plot. The default value is to use the global settings of **Rgraphviz**.
- lty: the line type of highlighted arcs. Possible values are 0, 1, 2, 3, 4, 5, 6, "blank", "solid", "dashed", "dotted", "dotdash", "longdash" and "twodash". The default value is to use the global settings of **Rgraphviz**.

Value

graphviz.plot returns invisibly the graph object produced by **Rgraphviz**.

`hailfinder` *The HailFinder weather forecast system (synthetic) data set*

Description

Hailfinder is a Bayesian network designed to forecast severe summer hail in northeastern Colorado.

Usage

```
data(hailfinder)
```

Format

The `hailfinder` data set contains the following 56 variables:

- `N07muVerMo` (*10.7mu vertical motion*): a four-level factor with levels `StrongUp`, `WeakUp`, `Neutral` and `Down`.
- `SubjVertMo` (*subjective judgment of vertical motion*): a four-level factor with levels `StrongUp`, `WeakUp`, `Neutral` and `Down`.
- `QGVertMotion` (*quasigeostrophic vertical motion*): a four-level factor with levels `StrongUp`, `WeakUp`, `Neutral` and `Down`.
- `CombVerMo` (*combined vertical motion*): a four-level factor with levels `StrongUp`, `WeakUp`, `Neutral` and `Down`.
- `AreaMesoALS` (*area of meso-alpha*): a four-level factor with levels `StrongUp`, `WeakUp`, `Neutral` and `Down`.
- `SatContMoist` (*satellite contribution to moisture*): a four-level factor with levels `VeryWet`, `Wet`, `Neutral` and `Dry`.
- `RaoContMoist` (*reading at the forecast center for moisture*): a four-level factor with levels `VeryWet`, `Wet`, `Neutral` and `Dry`.
- `CombMoisture` (*combined moisture*): a four-level factor with levels `VeryWet`, `Wet`, `Neutral` and `Dry`.
- `AreaMoDryAir` (*area of moisture and adry air*): a four-level factor with levels `VeryWet`, `Wet`, `Neutral` and `Dry`.
- `VISCloudCov` (*visible cloud cover*): a three-level factor with levels `Cloudy`, `PC` and `Clear`.
- `IRCloudCover` (*infrared cloud cover*): a three-level factor with levels `Cloudy`, `PC` and `Clear`.
- `CombClouds` (*combined cloud cover*): a three-level factor with levels `Cloudy`, `PC` and `Clear`.
- `CldShadeOth` (*cloud shading, other*): a three-level factor with levels `Cloudy`, `PC` and `Clear`.
- `AMInstabMt` (*AM instability in the mountains*): a three-level factor with levels `None`, `Weak` and `Strong`.
- `InsInMt` (*instability in the mountains*): a three-level factor with levels `None`, `Weak` and `Strong`.
- `WndHodograph` (*wind hodograph*): a four-level factor with levels `DCVZFavor`, `StrongWest`, `Westerly` and `Other`.

- OutflowFrMt (*outflow from mountains*): a three-level factor with levels None, Weak and Strong.
- MorningBound (*morning boundaries*): a three-level factor with levels None, Weak and Strong.
- Boundaries (*boundaries*): a three-level factor with levels None, Weak and Strong.
- CldShadeConv (*cloud shading, convection*): a three-level factor with levels None, Some and Marked.
- CompPlFcst (*composite plains forecast*): a three-level factor with levels IncCapDecIns, LittleChange and DecCapIncIns.
- CapChange (*capping change*): a three-level factor with levels Decreasing, LittleChange and Increasing.
- LoLevMoistAd (*low-level moisture advection*): a four-level factor with levels StrongPos, WeakPos, Neutral and Negative.
- InsChange (*instability change*): three-level factor with levels Decreasing, LittleChange and Increasing.
- MountainFcst (*mountains (region 1) forecast*): a three-level factor with levels XNIL, SIG and SVR.
- Date (*date*): a six-level factor with levels May15_Jun14, Jun15_Jul1, Jul2_Jul15, Jul16_Aug10, Aug11_Aug20 and Aug20_Sep15.
- Scenario (*scenario*): an eleven-level factor with levels A, B, C, D, E, F, G, H, I, J and K.
- ScenRelAMCIN (*scenario relevant to AM convective inhibition*): a two-level factor with levels AB and CThruK.
- MorningCIN (*morning convective inhibition*): a four-level factor with levels None, PartInhibit, Stifling and TotalInhibit.
- AMCINInScen (*AM convective inhibition in scenario*): a three-level factor with levels LessThanAve, Average and MoreThanAve.
- CapInScen (*capping withing scenario*): a three-level factor with levels LessThanAve, Average and MoreThanAve.
- ScenRelAMIns (*scenario relevant to AM instability*): a six-level factor with levels ABI, CDEJ, F, G, H and K.
- LIfr12ZDENSd (*LI from 12Z DEN sounding*): a four-level factor with levels LIGt0, N1GtLIGt_4, N5GtLIGt_8 and LILt_8.
- AMDewptCalPl (*AM dewpoint calculations, plains*): a three-level factor with levels Instability, Neutral and Stability.
- AMInsWliScen (*AM instability within scenario*): a three-level factor with levels LessUnstable, Average and MoreUnstable.
- InsSclInScen (*instability scaling within scenario*): a three-level factor with levels LessUnstable, Average and MoreUnstable.
- ScenRel34 (*scenario relevant to regions 2/3/4*): a five-level factor with levels ACEFK, B, D, GJ and HI.
- LatestCIN (*latest convective inhibition*): a four-level factor with levels None, PartInhibit, Stifling and TotalInhibit.
- LLIW (*LLIW severe weather index*): a four-level factor with levels Unfavorable, Weak, Moderate and Strong.

- CurPropConv (*current propensity to convection*): a four-level factor with levels None, Slight, Moderate and Strong.
- ScnRelPlFcst (*scenario relevant to plains forecast*): an eleven-level factor with levels A, B, C, D, E, F, G, H, I, J and K.
- PlainsFcst (*plains forecast*): a three-level factor with levels XNIL, SIG and SVR.
- N34StarFcst (*regions 2/3/4 forecast*): a three-level factor with levels XNIL, SIG and SVR.
- R5Fcst (*region 5 forecast*): a three-level factor with levels XNIL, SIG and SVR.
- Dewpoints (*dewpoints*): a seven-level factor with levels LowEverywhere, LowAtStation, LowSHighN, LowNHighS, LowMtsHighPl, HighEverywher, Other.
- LowLLapse (*low-level lapse rate*): a four-level factor with levels CloseToDryAd, Steep, ModerateOrLe and Stable.
- MeanRH (*mean relative humidity*): a three-level factor with levels VeryMoist, Average and Dry.
- MidLLapse (*mid-level lapse rate*): a three-level factor with levels CloseToDryAd, Steep and ModerateOrLe.
- MvmtFeatures (*movement of features*): a four-level factor with levels StrongFront, MarkedUpper, OtherRapid and NoMajor.
- RHRatio (*realtive humidity ratio*): a three-level factor with levels MoistMDryL, DryMMoistL and other.
- SfcWndShfDis (*surface wind shifts and discontinuities*): a seven-level factor with levels DenvCyclone, E_W_N, E_W_S, MovigFtorOt, DryLine, None and Other.
- SynForcng (*synoptic forcing*): a five-level factor with levels SigNegative, NegToPos, SigPositive, PosToNeg and LittleChange.
- TempDis (*temperature discontinuities*): a four-level factor with levels QStationary, Moving, None, Other.
- WindAloft (*wind aloft*): a four-level factor with levels LV, SWQuad, NWQuad, AllElse.
- WindFieldMt (*wind fields, mountains*): a two-level factor with levels Westerly and LVorOther.
- WindFieldPln (*wind fields, plains*): a six-level factor with levels LV, DenvCyclone, LongAnticyc, E_NE, SEquad and WidespdDnsl.

hybrid algorithms *Hybrid structure learning algorithms*

Description

Learn the structure of a Bayesian network with the Max-Min Hill Climbing (MMHC) and the more general 2-phase Restricted Maximization (RSMAX2) hybrid algorithms.

Usage

```
rsmax2(x, whitelist = NULL, blacklist = NULL, restrict, maximize = "hc",
  test = NULL, score = NULL, alpha = 0.05, B = NULL, ...,
  maximize.args = list(), optimized = TRUE, strict = FALSE, debug = FALSE)
mmhc(x, whitelist = NULL, blacklist = NULL, test = NULL, score = NULL,
  alpha = 0.05, B = NULL, ..., restart = 0, perturb = 1, max.iter = Inf,
  optimized = TRUE, strict = FALSE, debug = FALSE)
```

Arguments

x	a data frame containing the variables in the model.

whitelist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs to be included in the graph.
blacklist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs not to be included in the graph.
restrict	a character string, the constraint-based algorithm to be used in the "restrict" phase. Possible values are gs, iamb, fast.iamb, inter.iamb and mmpc. See bnlearn-package and the documentation of each algorithm for details.
maximize	a character string, the score-based algorithm to be used in the "maximize" phase. Possible values are hc and tabu. See bnlearn-package for details.
test	a character string, the label of the conditional independence test to be used by the constraint-based algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See bnlearn-package for details.
score	a character string, the label of the network score to be used in the score-based algorithm. If none is specified, the default score is the *Bayesian Information Criterion* for both discrete and continuous data sets. See bnlearn-package for details.
alpha	a numeric value, the target nominal type I error rate of the conditional independence test.
B	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the test argument is not a permutation test.
...	additional tuning parameters for the network score used by the score-based algorithm. See score for details.
maximize.args	a list of arguments to be passed to the score-based algorithm specified by maximize, such as restart for hill-climbing or tabu for tabu search.
restart	an integer, the number of random restarts for the score-based algorithm.
perturb	an integer, the number of attempts to randomly insert/remove/reverse an arc on every random restart.
max.iter	an integer, the maximum number of iterations for the score-based algorithm.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.
optimized	a boolean value. See bnlearn-package for details.
strict	a boolean value. If TRUE conflicting results in the learning process generate an error; otherwise they result in a warning.

Value

An object of class bn. See bn-class for details.

Note

mmhc is simply rshc with restrict set to mmpc and maximize set to hc.

insurance *Insurance evaluation network (synthetic) data set*

Description

Insurance is a network for evaluating car insurance risks.

Usage

```
data(insurance)
```

Format

The `insurance` data set contains the following 27 variables:

- `GoodStudent` (*good student*): a two-level factor with levels `False` and `True`.
- `Age` (*age*): a three-level factor with levels `Adolescent`, `Adult` and `Senior`.
- `SocioEcon` (*socio-economic status*): a four-level factor with levels `Prole`, `Middle`, `UpperMiddle` and `Wealthy`.
- `RiskAversion` (*risk aversion*): a four-level factor with levels `Psychopath`, `Adventurous`, `Normal` and `Cautious`.
- `VehicleYear` (*vehicle age*): a two-level factor with levels `Current` and `older`.
- `ThisCarDam` (*damage to this car*): a four-level factor with levels `None`, `Mild`, `Moderate` and `Severe`.
- `RuggedAuto` (*ruggedness of the car*): a three-level factor with levels `EggShell`, `Football` and `Tank`.
- `Accident` (*severity of the accident*): a four-level factor with levels `None`, `Mild`, `Moderate` and `Severe`.
- `MakeModel` (*car's model*): a five-level factor with levels `SportsCar`, `Economy`, `FamilySedan`, `Luxury` and `SuperLuxury`.
- `DrivQuality` (*driving quality*): a three-level factor with levels `Poor`, `Normal` and `Excellent`.
- `Mileage` (*mileage*): a four-level factor with levels `FiveThou`, `TwentyThou`, `FiftyThou` and `Domino`.

- `Antilock` (*ABS*): a two-level factor with levels `False` and `True`.
- `DrivingSkill` (*driving skill*): a three-level factor with levels `SubStandard`, `Normal` and `Expert`.
- `SeniorTrain` (*senior training*): a two-level factor with levels `False` and `True`.
- `ThisCarCost` (*costs for the insured car*): a four-level factor with levels `Thousand`, `TenThou`, `HundredThou` and `Million`.
- `Theft` (*theft*): a two-level factor with levels `False` and `True`.
- `CarValue` (*value of the car*): a five-level factor with levels `FiveThou`, `TenThou`, `TwentyThou`, `FiftyThou` and `Million`.
- `HomeBase` (*neighbourhood type*): a four-level factor with levels `Secure`, `City`, `Suburb` and `Rural`.
- `AntiTheft` (*anti-theft system*): a two-level factor with levels `False` and `True`.
- `PropCost` (*ratio of the cost for the two cars*): a four-level factor with levels `Thousand`, `TenThou`, `HundredThou` and `Million`.
- `OtherCarCost` (*costs for the other car*): a four-level factor with levels `Thousand`, `TenThou`, `HundredThou` and `Million`.
- `OtherCar` (*other cars involved in the accident*): a two-level factor with levels `False` and `True`.
- `MedCost` (*cost of the medical treatment*): a four-level factor with levels `Thousand`, `TenThou`, `HundredThou` and `Million`.
- `Cushioning` (*cushioning*): a four-level factor with levels `Poor`, `Fair`, `Good` and `Excellent`.
- `Airbag` (*airbag*): a two-level factor with levels `False` and `True`.
- `ILiCost` (*inspection cost*): a four-level factor with levels `Thousand`, `TenThou`, `HundredThou` and `Million`.
- `DrivHist` (*driving history*): a three-level factor with levels `Zero`, `One` and `Many`.

```

`learning.test` *Synthetic (discrete) data set to test learning algorithms*

Description

This a synthetic data set used as a test case in the **bnlearn** package.

Usage

```
data(learning.test)
```

Format

The `learning.test` data set contains the following variables:

- `A`, a three-level factor with levels `a`, `b` and `c`.
- `B`, a three-level factor with levels `a`, `b` and `c`.
- `C`, a three-level factor with levels `a`, `b` and `c`.
- `D`, a three-level factor with levels `a`, `b` and `c`.
- `E`, a three-level factor with levels `a`, `b` and `c`.
- `F`, a two-level factor with levels `a` and `b`.

Note

The R script to generate data from this network is shipped in the '`network.scripts`' directory of this package.

Examples

```
# load the data and build the correct network from the model string.
data(learning.test)
res = empty.graph(names(learning.test))
modelstring(res) = "[A][C][F][B|A][D|A:C][E|B:F]"
plot(res)
```

`lizards` *Lizards' perching behaviour data set*

Description

Real-world data set about the perching behaviour of two species of lizards in the South Bimini island, from Shoener (1968).

Usage

```
data(lizards)
```

Format

The `lizards` data set contains the following variables:

- `Species` (*the species of the lizard*): a two-level factor with levels `Sagrei` and `Distichus`.
- `Height` (*perch height*): a two-level factor with levels `high` (greater than 4.75 feet) and `low` (lesser or equal to 4.75 feet).
- `Diameter` (*perch diameter*): a two-level factor with levels `narrow` (greater than 4 inches) and `wide` (lesser or equal to 4 inches).

Examples

```
# load the data and build the correct network from the model string.
data(lizards)
res = empty.graph(names(lizards))
modelstring(res) = "[Species][Diameter|Species][Height|Species]"
plot(res)
table(lizards[, c(3,2,1)])

## Not run:
# This data set is useful as it offers nominal values for
# the conditional mutual information and X^2 tests.
ci.test("Height", "Diameter", "Species", test = "mi", data = lizards)
ci.test("Height", "Diameter", "Species", test = "x2", data = lizards)

## End(Not run)
```

`local discovery algorithms`

Local discovery structure learning algorithms

Description

Learn the skeleton of a directed acyclic graph (DAG) from data using the Max-Min Parents and Children (MMPC) and the Semi-Interleaved HITON-PC constraint-based algorithms. ARACNE and Chow-Liu learn an approximation of that structure using pairwise mutual information coefficients.

Usage

```
mmpc(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE)
si.hiton.pc(x, cluster = NULL, whitelist = NULL, blacklist = NULL, test = NULL,
  alpha = 0.05, B = NULL, debug = FALSE, optimized = TRUE, strict = FALSE)

aracne(x, whitelist = NULL, blacklist = NULL, mi = NULL, debug = FALSE)
chow.liu(x, whitelist = NULL, blacklist = NULL, mi = NULL, debug = FALSE)
```

Arguments

`x`	a data frame containing the variables in the model.
`cluster`	an optional cluster object from package **parallel**. See `parallel integration` for details and a simple example.
`whitelist`	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs to be included in the graph.
`blacklist`	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs not to be included in the graph.
`mi`	a character string, the estimator used for the pairwise (i.e. unconditional) mutual information coefficients in the ARACNE and Chow-Liu algorithms. Possible values are `mi` (discrete mutual information) and `mi-g` (Gaussian mutual information).
`test`	a character string, the label of the conditional independence test to be used in the algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See `bnlearn-package` for details.
`alpha`	a numeric value, the target nominal type I error rate.
`B`	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the `test` argument is not a permutation test.
`debug`	a boolean value. If `TRUE` a lot of debugging output is printed; otherwise the function is completely silent.

`optimized` a boolean value. See `bnlearn-package` for details.

`strict` a boolean value. If `TRUE` conflicting results in the learning process generate an error; otherwise they result in a warning.

Value

An object of class `bn`. See `bn-class` for details.

`marks` *Examination marks data set*

Description

Examination marks of 88 students on five different topics, from Mardia (1979).

Usage

```
data(marks)
```

Format

The marks data set contains the following variables, one for each topic in the examination:

- MECH (*mechanics*)
- VECT (*vectors*)
- ALG (*algebra*)
- ANL (*analysis*)
- STAT (*statistics*)

All are measured on the same scale (0-100).

Examples

```
# This is the undirected graphical model from Edwards (2000).
data(marks)
ug = empty.graph(names(marks))
arcs(ug, ignore.cycles = TRUE) = matrix(
  c("MECH", "VECT", "MECH", "ALG", "VECT", "MECH", "VECT", "ALG",
    "ALG",  "MECH", "ALG", "VECT", "ALG",  "ANL", "ALG",  "STAT",
    "ANL",  "ALG", "ANL",  "STAT", "STAT", "ALG", "STAT", "ANL"),
  ncol = 2, byrow = TRUE,
  dimnames = list(c(), c("from", "to")))
```

---

misc utilities *Miscellaneous utilities*

Description

Assign or extract various quantities of interest from an object of class bn of bn.fit.

Usage

```
## nodes
mb(x, node)
nbr(x, node)
parents(x, node)
parents(x, node, debug = FALSE) <- value
children(x, node)
children(x, node, debug = FALSE) <- value
in.degree(x, node)
out.degree(x, node)
```

```
root.nodes(x)
leaf.nodes(x)
nnodes(x)

## arcs
arcs(x)
arcs(x, ignore.cycles = FALSE, debug = FALSE) <- value
directed.arcs(x)
undirected.arcs(x)
incoming.arcs(x, node)
outgoing.arcs(x, node)
incident.arcs(x, node)
compelled.arcs(x)
reversible.arcs(x)
narcs(x)

## adjacency matrix
amat(x)
amat(x, ignore.cycles = FALSE, debug = FALSE) <- value

## graphs
nparams(x, data, debug = FALSE)
ntests(x)
whitelist(x)
blacklist(x)

## shared with the graph package.
# these used to be a simple nodes(x) function.
## S4 method for signature 'bn'
nodes(object)
## S4 method for signature 'bn.fit'
nodes(object)
# these used to be a simple degree(x, node) function.
## S4 method for signature 'bn'
degree(object, Nodes)
## S4 method for signature 'bn.fit'
degree(object, Nodes)
# re-label the nodes.
## S4 replacement method for signature 'bn'
nodes(object) <- value
## S4 replacement method for signature 'bn.fit'
nodes(object) <- value
```

Arguments

x,object	an object of class bn or bn.fit. The replacement form of parents, children, arcs and amat require an object of class bn.

node,Nodes	a character string, the label of a node.
value	either a vector of character strings (for parents and children), an adjacency matrix (for amat) or a data frame with two columns (optionally labeled "from" and "to", for arcs).
data	a data frame containing the data the Bayesian network was learned from. It's only needed if x is an object of class bn.
ignore.cycles	a boolean value. If TRUE the returned network will not be checked for cycles.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The number of parameters of a discrete Bayesian network is defined as the sum of the number of logically independent parameters of each node given its parents (Chickering, 1995). For Gaussian Bayesian networks the distribution of each node can be viewed as a linear regression, so it has a number of parameters equal to the number of the parents of the node plus one (the intercept) as per Neapolitan (2003).

Value

mb, nbr, nodes, parents, children, root.nodes and leaf.nodes return a vector of character strings.

arcs, directed.arcs, undirected.arcs, incoming.arcs, outgoing.arcs, incident.arcs, compelled.arcs, reversible.arcs, whitelist and blacklist return a matrix of two columns of character strings.

narcs and nnodes return the number of arcs and nodes in the graph, respectively.

amat returns a matrix of 0/1 integer values.

degree, in.degree, out.degree, nparams and ntests return an integer.

Author(s)

Marco Scutari

Examples

```
data(learning.test)
res = gs(learning.test)

##  the Markov blanket of A.
mb(res, "A")
```

```
## the neighbourhood of F.
nbr(res, "F")
## the arcs in the graph.
arcs(res)
## the nodes of the graph.
nodes(res)
## the adjacency matrix for the nodes of the graph.
amat(res)
## the parents of D.
parents(res, "D")
## the children of A.
children(res, "A")
## the root nodes of the graph.
root.nodes(res)
## the leaf nodes of the graph.
leaf.nodes(res)
## number of parameters of the Bayesian network.
res = set.arc(res, "A", "B")
nparams(res, learning.test)
```

`model string utilities`

Build a model string from a Bayesian network and vice versa

Description

Build a model string from a Bayesian network and vice versa.

Usage

```
modelstring(x)
modelstring(x, debug = FALSE) <- value

model2network(string, ordering = NULL, debug = FALSE)

## S3 method for class 'bn'
as.character(x, ...)
## S3 method for class 'character'
as.bn(x)
```

Arguments

`x`	an object of class `bn`. `modelstring` (but not its replacement form) accepts also objects of class `bn.fit`.
`string`	a character string describing the Bayesian network.
`ordering`	the labels of all the nodes in the graph; their order is the node ordering used in the construction of the `bn` object. If `NULL` the nodes are sorted alphabetically.
`value`	a character string, the same as the `string`.

debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.
...	extra arguments from the generic method (currently ignored).

Details

The strings returned by modelstring have the same format as the ones returned by the modelstring function in package **deal**; network structures may be easily exported to and imported from that package (via the model2network function).

Value

model2network and as.bn return an object of class bn; modelstring and as.character.bn return a character string.

Author(s)

Marco Scutari

Examples

```
data(learning.test)
res = set.arc(gs(learning.test), "A", "B")
res
modelstring(res)
res2 = model2network(modelstring(res))
res2
all.equal(res, res2)
```

---

naive.bayes *Naive Bayes classifiers*

Description

Create, fit and perform predictions with naive Bayes and Tree-Augmented naive Bayes (TAN) classifiers.

Usage

```
naive.bayes(x, training, explanatory)
## S3 method for class 'bn.naive'
predict(object, data, prior, ..., prob = FALSE, debug = FALSE)

tree.bayes(x, training, explanatory, whitelist = NULL, blacklist = NULL,
  mi = NULL, root = NULL, debug = FALSE)
## S3 method for class 'bn.tan'
predict(object, data, prior, ..., prob = FALSE, debug = FALSE)
```

Arguments

training	a character string, the label of the training variable.
explanatory	a vector of character strings, the labels of the explanatory variables.
object	an object of class bn.naive, either fitted or not.
x, data	a data frame containing the variables in the model, which must all be factors.
prior	a numeric vector, the prior distribution for the training variable. It is automatically normalized if not already so. The default prior is the probability distribution of the training variable in object.
whitelist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs to be included in the graph.
blacklist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs not to be included in the graph.
mi	a character string, the estimator used for the mutual information coefficients for the Chow-Liu algorithm in TAN. Possible values are mi (discrete mutual information) and mi-g (Gaussian mutual information).
root	a character string, the label of the explanatory variable to bre used as the root of the tree in the TAN classifier.
...	extra arguments from the generic method (currently ignored).
prob	a boolean value. If TRUE the posterior probabilities used for prediction are attached to the predicted values as an attribute called prob.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The naive.bayes functions creates the star-shaped Bayesian network form of a naive Bayes classifier; the training variable (the one holding the group each observation belongs to) is at the center of the star, and it has an outgoing arc for each explanatory variable.

If data is specified, explanatory will be ignored and the labels of the explanatory variables will be extracted from the data.

predict performs a supervised classification of the observations by assigning them to the group with the maximum posterior probability.

Value

naive.bayes returns an object of class c("bn.naive", "bn"), which behaves like a normal bn object unless passed to predict. tree.bayes returns an object of class c("bn.tan", "bn"), which again behaves like a normal bn object unless passed to predict.

predict returns a factor with the same levels as the training variable from data. If prob = TRUE, the posterior probabilities used for prediction are attached to the predicted values as an attribute called prob.

Note

Since **bnlearn** does not support networks containing both continuous and discrete variables, all variables in `data` must be discrete.

Ties in prediction are broken using *Bayesian tie breaking*, i.e. sampling at random from the tied values. Therefore, setting the random seed is required to get reproducible results.

`tan.tree` support whitelisting and blacklisting arcs but not their directions. Morevoer it is not possible to whitelist or blacklist arcs incident on `training`.

`predict` accepts either a `bn` or a `bn.fit` object as its first argument. For the former, the parameters of the network are fitted on `data`, that is, the observations whose class labels the function is trying to predict.

Friedman N, Geiger D, Goldszmidt M (1997). "Bayesian Network Classifiers". *Machine Learning*, **29**(2–3), 131–163.

Examples

```
data(learning.test)
# this is an in-sample prediction with naive Bayes (parameter learning
# is performed implicitly during the prediction).
bn = naive.bayes(learning.test, "A")
pred = predict(bn, learning.test)
table(pred, learning.test[, "A"])

# this is an in-sample prediction with TAN (parameter learning is
# performed explicitly with bn.fit).
tan = tree.bayes(learning.test, "A")
fitted = bn.fit(tan, learning.test, method = "bayes")
pred = predict(fitted, learning.test)
table(pred, learning.test[, "A"])

# this is an out-of-sample prediction, from a training test to a separate
# test set.
training.set = learning.test[1:4000, ]
test.set = learning.test[4001:5000, ]
bn = naive.bayes(training.set, "A")
fitted = bn.fit(bn, training.set)
pred = predict(fitted, test.set)
table(pred, test.set[, "A"])
```

node ordering utilities

Utilities dealing with partial node orderings

Description

Find the partial node ordering implied by a network or generate the blacklist implied by a complete node ordering.

Usage

```
node.ordering(x, debug = FALSE)
ordering2blacklist(nodes)
tiers2blacklist(nodes)
```

Arguments

x	an object of class bn or bn.fit.
nodes	a node ordering, see below.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

ordering2blacklist takes a vector of character strings (the labels of the nodes), which specifies a complete node ordering. An object of class bn or bn.fit; in that case, the node ordering is derived by the graph. In both cases, the blacklist returned by ordering2blacklist contains all the possible arcs that violate the specified node ordering.

tiers2blacklist takes (again) a vector of character strings (the labels of the nodes), which specifies a complete node ordering, or a list of character vectors, which specifies a partial node ordering. In the latter case, all arcs going from a node in a particular element of the list (sometimes known as *tier*) to a node in one of the previous elements are blacklisted. Arcs between nodes in the same element are not blacklisted.

Value

node.ordering returns a vector of character strings, an ordered set of node labels.

ordering2blacklist and tiers2blacklist return a sanitized blacklist (a two-column matrix, whose columns are labeled from and to).

Note

node.ordering and ordering2blacklist support only completely directed Bayesian networks.

Author(s)

Marco Scutari

Examples

```
data(learning.test)
res = gs(learning.test, optimized = TRUE)
ntests(res)
res = set.arc(res, "A", "B")
ord = node.ordering(res)
ord

## partial node ordering saves us two tests in the v-structure
## detection step of the algorithm.
ntests(gs(learning.test, blacklist = ordering2blacklist(ord)))

tiers2blacklist(list(LETTERS[1:3], LETTERS[4:6]))
```

---

parallel integration *bnlearn - snow/parallel package integration*

Description

How to use the **bnlearn** package with the parallel computing environment provided by the **snow** or **parallel** packages.

Parallel computing for constraint-based algorithms

```
# load parallel and bnlearn and rsprng.
> library(parallel)
> library(bnlearn)
> cl = makeCluster(2)
# check it works.

`plot.bn` *Plot a Bayesian network*

Description

Plot the graph associated with a small Bayesian network.

Usage

```
## S3 method for class 'bn'
plot(x, ylim = c(0,600), xlim = ylim, radius = 250,
  arrow = 35, highlight = NULL, color = "red", ...)
```

Arguments

`x`	an object of class `bn`.
`ylim`	a numeric vector with two components containing the range on y-axis.
`xlim`	a numeric vector with two components containing the range on x-axis.
`radius`	a numeric value containing the radius of the nodes.
`arrow`	a numeric value containing the length of the arrow heads.
`highlight`	a vector of character strings, representing the labels of the nodes (and corresponding arcs) to be highlighted.
`color`	an integer or character string (the highlight colour).
`...`	other parameters to be passed through to plotting functions.

Note

The following graphical parameters are always overridden:

- `axes` is set to `FALSE`.
- `xlab` is set to an empty string.
- `ylab` is set to an empty string.

Author(s)

Marco Scutari

See Also

graphviz.plot.

Examples

```
data(learning.test)
res = gs(learning.test)

plot(res)

## highlight node B and related arcs.
plot(res, highlight = "B")
## highlight B and its Markov blanket.
plot(res, highlight = c("B", mb(res, "B")))

## a more compact plot.
par(oma = rep(0, 4), mar = rep(0, 4), mai = rep(0, 4),
  plt = c(0.06, 0.94, 0.12, 0.88))
plot(res)
```

---

plot.bn.strength *Plot arc strengths derived from bootstrap*

Description

Plot arc strengths derived from bootstrap resampling.

Usage

```
## S3 method for class 'bn.strength'
plot(x, draw.threshold = TRUE, main = NULL,
  xlab = "arc strengths", ylab = "CDF(arc strengths)", ...)
```

Arguments

x	an object of class bn.strength.
draw.threshold	a boolean value. If TRUE, a dashed vertical line is drawn at the threshold.
main,xlab,ylab	character strings, the main title and the axes labels.
...	other graphical parameters.

Note

The xlim and ylim graphical parameters are always overridden.

Author(s)

Marco Scutari

Examples

```
data(learning.test)

start = random.graph(nodes = names(learning.test), num = 50)
netlist = lapply(start, function(net) {
  hc(learning.test, score = "bde", iss = 10, start = net) })
arcs = custom.strength(netlist, nodes = names(learning.test), cpdag = FALSE)
plot(arcs)
```

---

preprocess *Pre-process data to better learn Bayesian networks*

Description

Screen and transform the data to make them more suitable for structure and parameter learning.

Usage

```
# discretize continuous data into factors.
discretize(data, method, breaks = 3, ordered = FALSE, ..., debug = FALSE)
# screen continuous data for highly correlated pairs of variables.
dedup(data, threshold, debug = FALSE)
```

Arguments

data	a data frame containing numeric columns (for dedup) or a combination of numeric or factor columns (for).
threshold	a numeric value between zero and one, the absolute correlation used a threshold in screening highly correlated pairs.
method	a character string, either interval for *interval discretization*, quantile for *quantile discretization* (the default) or hartemink for *Hartemink's pairwise mutual information* method.
breaks	if method is set to hartemink, an integer number, the number of levels the variables are to be discretized into. Otherwise, a vector of integer numbers, one for each column of the data set, specifying the number of levels for each variable.
ordered	a boolean value. If TRUE the discretized variables are returned as ordered factors instead of unordered ones.
...	additional tuning parameters, see below.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

discretize takes a data frame of continuous variables as its first argument and returns a secdond data frame of discrete variables, transformed using of three methods: interval, quantile or hartemink.

dedup screens the data for pairs of highly correlated variables, and discards one in each pair.

Value

discretize returns a data frame with the same structure (number of columns, column names, etc.) as data, containing the discretized variables.

dedup returns a data frame with a subset of the columns of data.

Note

Hartemink's algorithm has been designed to deal with sets of homogeneous, continuous variables; this is the reason why they are initially transformed into discrete variables, all with the same number of levels (given by the ibreaks argument). Which of the other algorithms is used is specified by the idisc argument (quantile is the default). The implementation in bnlearn also handles sets of discrete variables with the same number of levels, which are treated as adjacent interval identifiers. This allows the user to perform the initial discretization with the algorithm of his choice, as long as all variables have the same number of levels in the end.

Author(s)

Marco Scutari

References

Hartemink A (2001). *Principled Computational Methods for the Validation and Discovery of Genetic Regulatory Networks*. Ph.D. thesis, School of Electrical Engineering and Computer Science, Massachusetts Institute of Technology.

Examples

```
data(gaussian.test)
d = discretize(gaussian.test, method = 'hartemink', breaks = 4, ibreaks = 20)
plot(hc(d))
d2 = dedup(gaussian.test)
```

---

rbn *Simulate random data from a given Bayesian network*

Description

Simulate random data from a given Bayesian network.

Usage

```
## S3 method for class 'bn'
rbn(x, n = 1, data, fit = "mle", ..., debug = FALSE)
## S3 method for class 'bn.fit'
rbn(x, n = 1, ..., debug = FALSE)
```

Arguments

x	an object of class bn or bn.fit.
n	a positive integer giving the number of observations to generate.
data	a data frame containing the data the Bayesian network was learned from.
fit	a character string, the label of the method used to fit the parameters of the newtork. See bn.fit for details.
...	additional arguments for the parameter estimation prcoedure, see again bn.fit for details..
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

A data frame with the same structure (column names and data types) of the data parameter (if x is an object of class bn) or with the same structure as the data originally used to to fit the parameters of the Bayesian network (if x is an object of class bn.fit).

Author(s)

Marco Scutari

References

Korb K, Nicholson AE (2010). *Bayesian Artificial Intelligence*. Chapman & Hall/CRC, 2nd edition.

See Also

bn.boot, bn.cv.

Examples

```
## Not run:
data(learning.test)
res = gs(learning.test)
res = set.arc(res, "A", "B")
par(mfrow = c(1,2))
plot(res)
sim = rbn(res, 500, learning.test)
plot(gs(sim))
## End(Not run)
```

relevant *Identify Relevant Nodes Without Learning the Bayesian network*

Description

Identify all the nodes relevant to compute all the conditional probability distributions for a given set of nodes.

Usage

```
relevant(target, context, data, test, alpha, B, debug = FALSE)
```

Arguments

target	a vector of character strings, the labels of nodes whose conditional probability distributions are of interest.
context	a vector of character strings, the labels of nodes on which to condition the independence tests.
data	a data frame containing either numeric or factor columns.
test	a character string, the label of the conditional independence test to be used in the algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See bnlearn-package for details.
alpha	a numeric value, the target nominal type I error rate. If none is specified, the default value is 0.05.
B	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the test argument is not a permutation test.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

relevant returns a vector of character strings, the labels of the relevant nodes.

Note

This algorithms selects all the nodes that are relevant at all, not only those that are significantly so. Therefore, to be discarded a node must be completely unrelated to any of the target nodes, not just weakly dependent. On the good side, relevant nodes are correctly identified even for data sets whose probability structure is not faithful to any directed acyclic graph.

Author(s)

Marco Scutari

References

Pena JM, Nilsson R, Bjorkegren J, Tegner J (2006). "Identifying the Relevant Nodes Without Learning the Model". In "Proceedings of the 22nd Conference on Uncertainty in Artificial Intelligence (UAI2006)", pp. 367-374.

Examples

```
data(learning.test)
X = as.factor(sample(c("x1", "x2"), nrow(learning.test), replace = TRUE))
relevant("A", data = cbind(learning.test, X))
relevant("A", context = "B", data = learning.test,)
```

---

score *Score of the Bayesian network*

Description

Compute the score of the Bayesian network.

Usage

```
score(x, data, type = NULL, ..., debug = FALSE)

## S3 method for class 'bn'
logLik(object, data, ...)
## S3 method for class 'bn'
AIC(object, data, ..., k = 1)
## S3 method for class 'bn'
BIC(object, data, ...)
```

Arguments

x, object	an object of class bn.
data	a data frame containing the data the Bayesian network was learned from.
type	a character string, the label of a network score. If none is specified, the default score is the *Bayesian Information Criterion* for both discrete and continuous data sets. See bnlearn-package for details.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.
...	extra arguments from the generic method (for the AIC and logLik functions, currently ignored) or additional tuning parameters (for the score function).
k	a numeric value, the penalty per parameter to be used; the default k = 1 gives the expression used to compute the AIC in the context of scoring Bayesian networks.

Details

Additional parameters of the `score` function:

- `iss`: the imaginary sample size, used by the Bayesian Dirichlet equivalent score (both the `bde` and `mbde`) and the Bayesian Gaussian score (`bge`). It is also known as "equivalent sample size". The default value is equal to `10` for both the `bde`/`mbde` scores and `bge`.
- `exp`: a list of indexes of experimental observations (those that have been artificially manipulated). Each element of the list must be named after one of the nodes, and must contain a numeric vector with indexes of the observations whose value has been manipulated for that node.
- `k`: the penalty per parameter to be used by the AIC and BIC scores. The default value is `1` for AIC and `log(nrow(data))/2` for BIC.
- `phi`: the prior phi matrix formula to use in the Bayesian Gaussian equivalent (`bge`) score. Possible values are `heckerman` (default) and `bottcher` (the one used by default in the **deal** package.)
- `prior`: the prior distribution to be used with the Bayesian Dirichlet equivalent score (`bde`) and the Bayesian Gaussian score (`bge`). Possible values are `uniform` (the default), `vsp` (the Bayesian variable selection prior, which puts a probability of inclusion on parents) and `cs` (the Castelo & Siebes prior, which puts an independent prior probability on each arc and direction).
- `beta`: the parameter associated with `prior`. If `prior` is `uniform`, `beta` is ignored. If `prior` is `vsp`, `beta` is the probability of inclusion of an additional parent (the default is `1/ncol(data)`). If `prior` is `cs`, `beta` is a data frame with columns `from`, `to` and `prob` specifying the prior probability for a set of arcs. A uniform probability distribution is assumed for the remaining arcs.

Value

A numeric value, the score of the Bayesian network.

Note

AIC and BIC are computed as `logLik(x) - k * nparams(x)`, that is, the classic definition rescaled by -2. Therefore higher values are better, and for large sample sizes BIC converges to log(BDe).

score-based algorithms

Score-based structure learning algorithms

Description

Learn the structure of a Bayesian network using a hill-climbing (HC) or a Tabu search (TABU) greedy search.

Usage

```
hc(x, start = NULL, whitelist = NULL, blacklist = NULL, score = NULL, ...,
  debug = FALSE, restart = 0, perturb = 1, max.iter = Inf, maxp = Inf, optimized = TRUE)
tabu(x, start = NULL, whitelist = NULL, blacklist = NULL, score = NULL, ...,
  debug = FALSE, tabu = 10, max.tabu = tabu, max.iter = Inf, maxp = Inf, optimized = TRUE)
```

Arguments

x	a data frame containing the variables in the model.
start	an object of class bn, the preseeded directed acyclic graph used to initialize the algorithm. If none is specified, an empty one (i.e. without any arc) is used.
whitelist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs to be included in the graph.
blacklist	a data frame with two columns (optionally labeled "from" and "to"), containing a set of arcs not to be included in the graph.
score	a character string, the label of the network score to be used in the algorithm. If none is specified, the default score is the *Bayesian Information Criterion* for both discrete and continuous data sets. See bnlearn-package for details.
...	additional tuning parameters for the network score. See score for details.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.
restart	an integer, the number of random restarts.
tabu	a positive integer number, the length of the tabu list used in the tabu function.
max.tabu	a positive integer number, the iterations tabu search can perform without improving the best network score.
perturb	an integer, the number of attempts to randomly insert/remove/reverse an arc on every random restart.
max.iter	an integer, the maximum number of iterations.
maxp	the maximum number of parents for a node. The default value is Inf.
optimized	a boolean value. See bnlearn-package for details.

Value

An object of class bn. See bn-class for details.

single-node local discovery

Discover the structure around a single node

Description

Learn the Markov blanket or the neighbourhood centered on a node.

Usage

```
learn.mb(x, node, method, whitelist = NULL, blacklist = NULL, start = NULL,
  test = NULL, alpha = 0.05, B = NULL, debug = FALSE)
learn.nbr(x, node, method, whitelist = NULL, blacklist = NULL, start = NULL,
  test = NULL, alpha = 0.05, B = NULL, debug = FALSE)
```

Arguments

`x`	a data frame containing the variables in the model.
`node`	a character string, the label of the node whose local structure is being learned.
`method`	a character string, the label of a structure learning algorithm. Possible choices are constraint-based algorithms for `learn.mb` and local discovery algorithms for `learn.nbr`.
`whitelist`	a vector of character strings, the labels of the whitelisted nodes.
`blacklist`	a vector of character strings, the labels of the blacklisted nodes.
`start`	a vector of character strings, the labels of the nodes to be included in the Markov blanket before the learning process (in `learn.mb`). Note that the nodes in `start` can be removed from the Markov blanket by the learning algorithm, unlike the nodes included due to whitelisting.
`test`	a character string, the label of the conditional independence test to be used in the algorithm. If none is specified, the default test statistic is the *mutual information* for categorical variables, the Jonckheere-Terpstra test for ordered factors and the *linear correlation* for continuous variables. See `bnlearn-package` for details.
`alpha`	a numeric value, the target nominal type I error rate.

B	a positive integer, the number of permutations considered for each permutation test. It will be ignored with a warning if the conditional independence test specified by the test argument is not a permutation test.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Value

A vector of character strings, the labels of the nodes in the Markov blanket (for learn.mb) or in the neighbourhood (for learn.nbr).

strength.plot *Arc strength plot*

Description

Plot a Bayesian network and format its arcs according to the strength of the dependencies they represent. Requires the **Rgraphviz** package.

Usage

```
strength.plot(x, strength, threshold, cutpoints, highlight = NULL,
  layout = "dot", shape = "circle", main = NULL, sub = NULL, debug = FALSE)
```

Arguments

x	an object of class bn.
strength	an object of class bn.strength computed from the object of class bn corresponding to the x parameter.
threshold	a numeric value. See below.
cutpoints	an array of numeric values. See below.
highlight	a list, see graphviz.plot for details.
layout	a character string, the layout parameter to be passed to **Rgraphviz**. Possible values are dots, neato, twopi, circo and fdp. See **Rgraphviz** documentation for details.
shape	a character string, the shape of the nodes. Can be circle, ellipse or rectangle.
main	a character string, the main title of the graph. It's plotted at the top of the graph.
sub	a character string, a subtitle which is plotted at the bottom of the graph.
debug	a boolean value. If TRUE a lot of debugging output is printed; otherwise the function is completely silent.

Details

The `threshold` parameter is used to determine which arcs are supported strongly enough by the data to be deemed significant:

- if arc strengths have been computed using conditional independence tests, any strength coefficient (which is the p-value of the test) lesser or equal than the threshold is considered significant. In this case the default value of `threshold` is equal to the value of the `alpha` parameter used in the call to `arc.strength`, which in turn defaults to the one used by the learning algorithm (if any) or to `0.05`.
- if arc strengths have been computed using network scores, any strength coefficient (which is the increase/decrease of the network score caused by the removal of the arc) lesser than the threshold is considered significant. In this case the default value of `threshold` is `0`.
- if arc strengths have been computed using bootstrap, any strength coefficient (which is the relative frequency of the arc in the networks learned from the bootstrap replicates) greater or equal than the threshold is considered significant. In this case the default value of `threshold` is `0.5`.

Non-significant arcs are plotted as dashed lines.

The `cutpoints` parameter is an array of numeric values used to divide the range of the strength coefficients into intervals. The interval each strength coefficient falls into determines the line width of the corresponding arc in the plot. The default intervals are delimited by

```
unique(c(0, threshold/c(10, 5, 2, 1.5, 1), 1))
```

if the coefficients are computed from conditional independence tests, by

```
1 - unique(c(0, threshold/c(10, 5, 2, 1.5, 1), 1))
```

for bootstrap estimates or by the quantiles

```
quantile(-s[s < threshold], c(0.50, 0.75, 0.90, 0.95, 1))
```

of the significant coefficients if network scores are used.

Value

The object of class `graphAM` used to format and render the plot. It can be further modified using the commands present in the **graph** and **Rgraphviz** packages.

Author(s)

Marco Scutari

Examples

```
## Not run:
# plot the network learned by gs().
res = set.arc(gs(learning.test), "A", "B")
strength = arc.strength(res, learning.test, criterion = "x2")
strength.plot(res, strength)
# add another (non-significant) arc and plot the network again.
res = set.arc(res, "A", "C")
strength = arc.strength(res, learning.test, criterion = "x2")
```

```
strength.plot(res, strength)

## End(Not run)
```

`test counter` *Manipulating the test counter*

Description

Check, increment or reset the test/score counter used in structure learning algorithms.

Usage

```
test.counter()
increment.test.counter(i = 1)
reset.test.counter()
```

Arguments

`i`	a numeric value, which is added to the test counter.

Value

A numeric value, the current value of the test counter.

Author(s)

Marco Scutari

Examples

```
data(learning.test)
hc(learning.test)
test.counter()
reset.test.counter()
test.counter()
```
